Chicago, Illinois, U.S.A.

PREFACE

The study of the history of mathematical notations was suggested to me by Professor E. H. Moore, of the University of Chicago. To him and to Professor M.W. Haskell, of the University of California, I am indebted for encouragement in the pursuit of this research. As completed in August, 1925, the present history was intended to be brought out in one volume. To Professor H. E. Slaught, of the University of Chicago, I owe the suggestion that the work be divided into two volumes, of which the first should limit itself to the history of symbols in elementary mathematics, since such a volume would appeal to a wider constituency of readers than would be the case with the part on symbols in higher mathematics. To Professor Slaught I also owe generous and vital assistance in many other ways. He examined the entire manuscript of this work in detail, and brought it to the sympathetic attention of the Open Court Publishing Company. I desire to record my gratitude to Mrs. Mary Hegeler Carus, president of the Open Court Publishing Company, for undertaking this expensive publication from which no financial profits can be expected to accrue.

I gratefully acknowledge the assistance in the reading of the proofs of part of this history rendered by Professor Haskell, of the University of California; Professor R. C. Archibald, of Brown University; and Professor L. C. Karpinski, of the University of Michigan.

I

INTRODUCTION

In this history it has been an aim to give not only the first appearance of a symbol and its origin (whenever possible), but also to indicate the competition encountered and the spread of the symbol among writers in different countries. It is the latter part of our program which has given bulk to this history.

The rise of certain symbols, their day of popularity, and their eventual decline constitute in many cases an interesting story. Our endeavor has been to do justice to obsolete and obsolescent notations, as well as to those which have survived and enjoy the favor of mathematicians of the present moment.

If the object of this history of notations were simply to present an array of facts, more or less interesting to some students of mathematics—if, in other words, this undertaking had no ulterior motive—then indeed the wisdom of preparing and publishing so large a book might be questioned. But the author believes that this history constitutes a mirror of past and present conditions in mathematics which can be made to bear on the notational problems now confronting mathematics. The successes and failures of the past will contribute to a more speedy solution of the notational problems of the present time.

II

NUMERAL SYMBOLS AND COMBINATIONS OF SYMBOLS

BABYLONIANS

1. In the Babylonian notation of numbers a vertical wedge Υ stood for 1, while the characters \lessdot and $\Upsilon\lessdot$ signified 10 and 100, respectively. Grotefend¹ believes the character for 10 originally to have been the picture of two hands, as held in prayer, the palms being pressed together, the fingers close to each other, but the thumbs thrust out. Ordinarily, two principles were employed in the Babylonian notation—the additive and multiplicative. We shall see that limited use was made of a third principle, that of subtraction.

2. Numbers below 200 were expressed ordinarily by symbols whose respective values were to be *added*. Thus, $\Upsilon\lessdot\lessdot\lessdot\Upsilon\Upsilon\Upsilon$ stands for 123. The principle of multiplication reveals itself in $\lessdot\Upsilon\lessdot$ where the smaller symbol 10, placed before the 100, is to be multiplied by 100, so that this symbolism designates 1,000.

3. These cuneiform symbols were probably invented by the early Sumerians. Their inscriptions disclose the use of a decimal scale of numbers and also of a *sexagesimal* scale.²

Early Sumerian clay tablets contain also numerals expressed by circles and curved signs, made with the blunt circular end of a stylus, the ordinary wedge-shaped characters being made with the pointed end. A circle \bullet stood for 10, a semicircular or lunar sign stood for 1. Thus, a "round-up" of cattle shows $\bullet\bullet\frac{\circ}{\circ\circ\circ}$, or 36, cows.³

4. The sexagesimal scale was first discovered on a tablet by E. Hincks⁴ in 1854. It records the magnitude of the illuminated portion

¹ His first papers appeared in *Göttingische Gelehrte Anzeigen* (1802), Stück 149 und 178; *ibid.* (1803), Stück 60 und 117.

² In the division of the year and of the day, the Babylonians used also the duodecimal plan.

³ G. A. Barton, *Haverford Library Collection of Tablets*, Part I (Philadelphia, 1905), Plate 3, HCL 17, obverse; see also Plates 20, 26, 34, 35. Allotte de la Fuye, "En-e-tar-zi patési de Lagaš," *H. V. Hilprecht Anniversary Volume* (Chicago, 1909), p. 128, 133.

⁴ "On the Assyrian Mythology," *Transactions of the Royal Irish Academy. "Polite Literature,"* Vol. XXII, Part 6 (Dublin, 1855), p. 406, 407.

of the moon's disk for every day from new to full moon, the whole disk being assumed to consist of 240 parts. The illuminated parts during the first five days are the series 5, 10, 20, 40, 1.20, which is a geometrical progression, on the assumption that the last number is 80. From here on the series becomes arithmetical, 1.20, 1.36, 1.52, 2.8, 2.24, 2.40, 2.56, 3.12, 3.28, 3.44, 4, the common difference being 16. The last number is written in the tablet , and, according to Hincks's interpretation, stood for $4 \times 60 = 240$.

FIG. 1.—Babylonian tablets from Nippur, about 2400 B.C.

5. Hincks's explanation was confirmed by the decipherment of tablets found at Senkereh, near Babylon, in 1854, and called the *Tablets of Senkereh*. One tablet was found to contain a table of square numbers, from 1^2 to 60^2 , a second one a table of cube numbers from 1^3 to 32^3 . The tablets were probably written between 2300 and 1600 B.C. Various scholars contributed toward their interpretation. Among them were George Smith (1872), J. Oppert, Sir H. Rawlinson, Fr. Lenormant, and finally R. Lepsius.¹ The numbers 1, 4, 9, 16, 25, 36,

Oppert, *Étalon des mesures assyr. fixé par les textes cunéiformes* (Paris, 1874); Sir H. Rawlinson and G. Smith, "The Cuneiform Inscriptions of Western Asia," Vol. IV: *A Selection from the Miscellaneous Inscriptions of Assyria* (London, 1875), Plate 40; R. Lepsius, "Die Babylonisch-Assyrischen Längenmaasse nach der Tafel von Senkereh," *Abhandlungen der Königlichen Akademie der Wissenschaften zu Berlin* (aus dem Jahre 1877 [Berlin, 1878], Philosophisch-historische Klasse), p. 105–44.

and 49 are given as the squares of the first seven integers, respectively. We have next $1.4 = 8^2$, $1.21 = 9^2$, $1.40 = 10^2$, etc. This clearly indicates the use of the sexagesimal scale which makes $1.4 = 60 + 4$, $1.21 = 60 + 21$, $1.40 = 60 + 40$, etc. This sexagesimal system marks the earliest appearance of the all-important "principle of position" in written numbers. In its general and systematic application, this principle requires a symbol for zero. But no such symbol has been found on Babylonian tablets; records of about 200 B.C. give a symbol for zero, as we shall see later, but it was not used in calculation. The earliest thorough and systematic application of a symbol for zero and the principle of position was made by the Maya of Central America, at the beginning of the Christian Era.

6. An extension of our knowledge of Babylonian mathematics was made by H. V. Hilprecht who made excavations at Nuffar (ancient Nippur). We reproduce one of his tablets¹ in Figure 1.

Hilprecht's transliteration, as given on page 28 of his text, is as follows:

Line 1.	125	720	Line 9.	2,000
Line 2.	IGI-GAL-BI	103,680	Line 10.	IGI-GAL-BI
Line 3.	250	360	Line 11.	4,000
Line 4.	IGI-GAL-BI	51,840	Line 12.	IGI-GAL-BI
Line 5.	500	180	Line 13.	8,000
Line 6.	IGI-GAL-BI	25,920	Line 14.	IGI-GAL-BI
Line 7.	1,000	90	Line 15.	16,000
Line 8.	IGI-GAL-BI	12,960	Line 16.	IGI-GAL-BI

7. In further explanation, observe that in

Line 1.	$125 = 2 \times 60 + 5,$	$720 = 12 \times 60 + 0$
Line 2.	Its denominator,	$103,680 = [28 \times 60 + 48(?)] \times 60$
Line 3.	$250 = 4 \times 60 + 10,$	$360 = 6 \times 60 + 0$
Line 4.	Its denominator,	$51,840 = [14 \times 60 + 24] \times 60 + 0$
Line 5.	$500 = 8 \times 60 + 20,$	$180 = 3 \times 60 + 0$
Line 6.	Its denominator,	$25,920 = [7 \times 60 + 12] \times 60 + 0$
Line 7.	$1,000 = 16 \times 60 + 40,$	$90 = 1 \times 60 + 30$
Line 8.	Its denominator,	$12,960 = [3 \times 60 + 36] \times 60 + 0$

¹ *The Babylonian Expedition of the University of Pennsylvania. Series "Cuneiform Texts," Vol. XX, Part 1. Mathematical, Metrological and Chronological Tablets from the Temple Library of Nippur* (Philadelphia, 1906), Plate No. 25.

Line 9.	$2,000 = 33 \times 60 + 20,$	$18 = 10 + 8$
Line 10.	Its denominator,	$6,480 = [1 \times 60 + 48] \times 60 + 0$
Line 11.	$4,000 = [1 \times 60 + 6] \times 60 + 40,$	9
Line 12.	Its denominator,	$3,240 = 54 \times 60 + 0$
Line 13.	$8,000 = [2 \times 60 + 13] \times 60 + 20,$	18
Line 14.	Its denominator,	$1,620 = 27 \times 60 + 0$
Line 15.	$16,000 = [4 \times 60 + 26] \times 60 + 40,$	9
Line 16.	Its denominator,	$810 = 13 \times 60 + 30$
<i>IGI-GAL</i> = Denominator, <i>BI</i> = Its, i.e., the number 12,960,000 or 60^4 .		

We quote from Hilprecht (*op. cit.*, pp. 28-30):

"We observe (a) that the first numbers of all the odd lines (1, 3, 5, 7, 9, 11, 13, 15) form an increasing, and all the numbers of the even lines (preceded by *IGI-GAL-BI* = 'its denominator') a descending geometrical progression; (b) that the first number of every odd line can be expressed by a fraction which has 12,960,000 as its numerator and the closing number of the corresponding even line as its denominator, in other words,

$$\begin{aligned}
 125 &= \frac{12,960,000}{103,680} ; & 250 &= \frac{12,960,000}{51,840} ; & 500 &= \frac{12,960,000}{25,920} ; \\
 1,000 &= \frac{12,960,000}{12,960} ; & 2,000 &= \frac{12,960,000}{6,480} ; & 4,000 &= \frac{12,960,000}{3,240} ; \\
 8,000 &= \frac{12,960,000}{1,620} ; & 16,000 &= \frac{12,960,000}{810} .
 \end{aligned}$$

But the closing numbers of all the odd lines (720, 360, 180, 90, 18, 9, 18, 9) are still obscure to me. . . .

"The question arises, what is the meaning of all this? What in particular is the meaning of the number 12,960,000 ($= 60^4$ or $3,600^2$) which underlies all the mathematical texts here treated . . . ? . . . This 'geometrical number' (12,960,000), which he [Plato in his *Republic* viii. 546B-D] calls 'the lord of better and worse births,' is the arithmetical expression of a great law controlling the Universe. According to Adam this law is 'the Law of Change, that law of inevitable degeneration to which the Universe and all its parts are subject'—an interpretation from which I am obliged to differ. On the contrary, it is the Law of Uniformity or Harmony, i.e. that fundamental law which governs the Universe and all its parts, and which cannot be ignored and violated without causing an anomaly, i.e. without resulting in a degeneration of the race." The nature of the "Platonic number" is still a debated question.

8. In the reading of numbers expressed in the Babylonian sexagesimal system, uncertainty arises from the fact that the early Babylonians had no symbol for zero. In the foregoing tablets, how do we know, for example, that the last number in the first line is 720 and not 12? Nothing in the symbolism indicates that the 12 is in the place where the local value is "sixties" and not "units." Only from the study of the entire tablet has it been inferred that the number intended is 12×60 rather than 12 itself. Sometimes a horizontal line was drawn following a number, apparently to indicate the absence of units of lower denomination. But this procedure was not regular, nor carried on in a manner that indicates the number of vacant places.

9. To avoid confusion some Babylonian documents even in early times contained symbols for 1, 60, 3,600, 216,000, also for 10, 600, 36,000.¹ Thus \cdot was 10, \bullet was 3,600, \odot was 36,000.

in view of other variants occurring in the mathematical tablets from Nippur, notably the numerous variants of "19," some of which may be merely scribal errors:

They evidently all go back to the form  or  ($20 - 1 = 19$).

FIG. 2.—Showing application of the principle of subtraction

10. Besides the principles of addition and multiplication, Babylonian tablets reveal also the use of the principle of subtraction, which is familiar to us in the Roman notation XIX ($20 - 1$) for the number 19. Hilprecht has collected ideograms from the Babylonian tablets which he has studied, which represent the number 19. We reproduce his symbols in Figure 2. In each of these twelve ideograms (Fig. 2), the two symbols to the left signify together 20. Of the symbols immediately to the right of the 20, one vertical wedge stands for "one" and the remaining symbols, for instance Υ , for LAL or "minus"; the entire ideogram represents in each of the twelve cases the number $20 - 1$ or 19.

One finds the principle of subtraction used also with curved signs;² $\bullet \odot \bullet \Upsilon$ meant $60 + 20 - 1$, or 79.

¹ See François Thureau-Dangin, *Recherches sur l'origine de l'écriture cunéiforme* (Paris, 1898), Nos. 485-91, 509-13. See also G. A. Barton, *Haverford College Library Collection of Cuneiform Tablets*, Part I (Philadelphia, 1905), where the forms are somewhat different; also the *Hilprecht Anniversary Volume* (Chicago, 1909), p. 128 ff.

² G. A. Barton, *op. cit.*, Plate 3, obverse.

11. The symbol used about the second century B.C. to designate absence of a number, or a blank space, is shown in Figure 3, concerning numerical data relating to the moon.¹ As previously stated, the symbol, \lesssim , was not used in computation and therefore performed

FIG. 3.—Babylonian lunar tables, reverse; full moon for one year, about the 1st of the second century B.C.

ly a small part of the functions of our modern zero. The symbol is shown in the tablet in row 10, column 12; also in row 8, column 13. Kugler's translation of the tablet, given in his book, page 42, is shown below. Of the last column only an indistinct fragment is preserved; the rest is broken off.

¹ Franz Xaver Kugler, S. J., *Die babylonische Mondrechnung* (Freiburg im Breisgau, 1900), Plate IV, No. 99 (81-7-6), lower part.

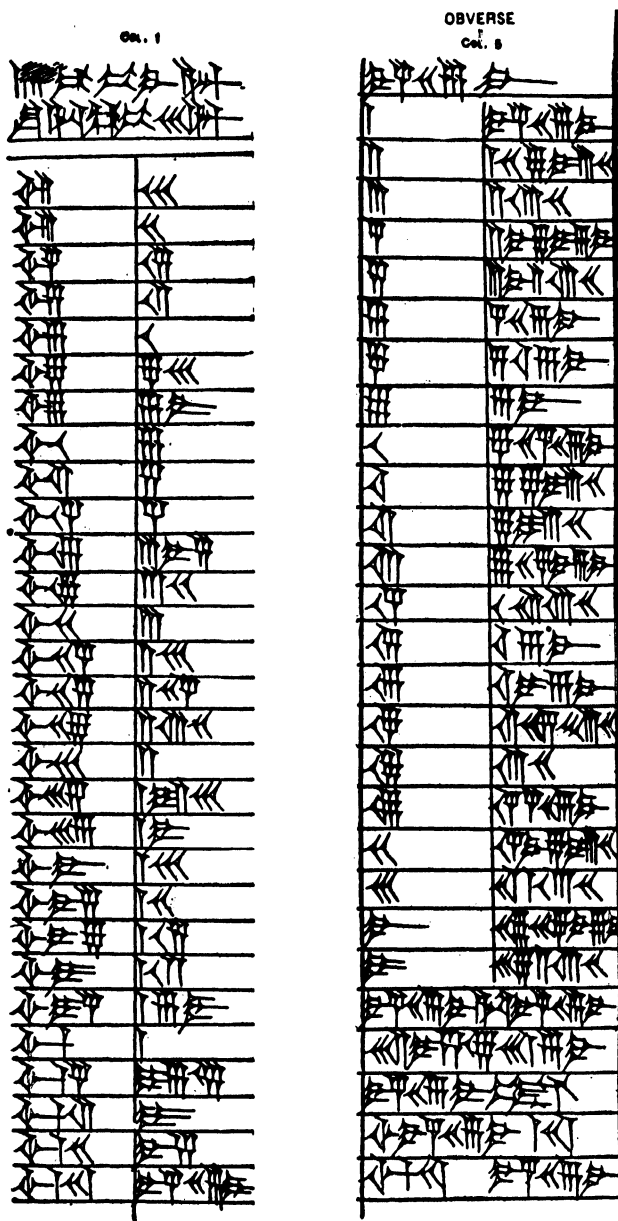

FIG. 4.—Mathematical cuneiform tablet, CBS 8536, in the Museum of the University of Pennsylvania.

12. J. Oppert pointed out the Babylonian use of a designation the sixths, viz., $\frac{1}{6}$, $\frac{1}{3}$, $\frac{1}{2}$, $\frac{2}{3}$, $\frac{5}{6}$. These are unit fractions or fractions whose numerators are one less than the denominators.¹ He also adduced evidence pointing to the Babylonian use of sexagesimal fractions and the use of the sexagesimal system in weights and measures. The occurrence of sexagesimal fractions is shown in tablets recently mined. We reproduce in Figure 4 two out of twelve columns found on a tablet described by H. F. Lutz.² According to Lutz, the tablet cannot be placed later than the Cassite period, but it seems more probable that it goes back even to the First Dynasty period, *ca.* 2000 B.C."

13. To mathematicians the tablet is of interest because it reveals operations with sexagesimal fractions resembling modern operations with decimal fractions. For example, 60 is divided by 81 and the quotient expressed sexagesimally. Again, a sexagesimal number with two fractional places, 44(26)(40), is multiplied by itself, yielding a product in four fractional places, namely, [32]55(18)(31)(6)(40). In this notation the [32] stands for 32×60 units, and to the (18), (31), (6), (40) must be assigned, respectively, the denominators 60, 60^2 , 60^3 , 60^4 .

The tablet contains twelve columns of figures. The first column (Fig. 4) gives the results of dividing 60 in succession by twenty-nine different divisors from 2 to 81. The eleven other columns contain tables of multiplication; each of the numbers 50, 48, 45, 44(26)(40), 36, 30, 25, 24, 22(30), 20 is multiplied by integers up to 20, then by the numbers 30, 40, 50, and finally by itself. Using our modern numerals, we interpret on page 10 the first and the fifth columns. They exhibit a larger number of fractions than do the other columns. The Babylonians had no mark separating the fractional from the integral parts of a number. Hence a number like 44(26)(40) might be interpreted in different ways; among the possible meanings are $44 \times 60 + 26 \times 60 + 40$, $44 \times 60 + 26 + 40 \times 60^{-1}$, and $44 + 26 \times 60^{-1} + 40 \times 60^{-2}$. Which interpretation is the correct one can be judged only by the context, if at all.

The exact meaning of the first two lines in the first column is uncertain. In this column 60 is divided by each of the integers written on the left. The respective quotients are placed on the right.

¹ Symbols for such fractions are reproduced also by Thureau-Dangin, *op. cit.*, pp. 481-84, 492-508, and by G. A. Barton, *Haverford College Library Collection of Cuneiform Tablets*, Part I (Philadelphia, 1905).

² "A Mathematical Cuneiform Tablet," *American Journal of Semitic Languages and Literatures*, Vol. XXXVI (1920), p. 249-57.

In the fifth column the multiplicand is $44(26)(40)$ or $44\frac{1}{3}$. The last two lines seem to mean " $60^2 \div 44(26)(40) = 81$, $60^2 \div 81 = 44(26)(40)$."

Numbers that are incorrect are marked by an asterisk (*).

14. The Babylonian use of sexagesimal fractions is shown also in a clay tablet described by A. Ungnad.¹ In it the diagonal of a rectangle whose sides are 40 and 10 is computed by the approximation

¹ *Orientalische Literaturzeitung* (ed. Peise, 1916), Vol. XIX, p. 363-68. See also Bruno Meissner, *Babylonien und Assyrien* (Heidelberg, 1925), Vol. II, p. 393.

$40+2\times 40\times 10^2\div 60^2$, yielding 42(13)(20), and also by the approximation $40+10^2\div \{2\times 40\}$, yielding 41(15). Translated into the decimal scale, the first answer is 42.22+, the second is 41.25, the true value being 41.23+. These computations are difficult to explain, except on the assumption that they involve sexagesimal *fractions*.

15. From what has been said it appears that the Babylonians had ideograms which, transliterated, are *Igi-Gal* for "denominator" or "division," and *Lal* for "minus." They had also ideograms which, transliterated, are *Igi-Dua* for "division," and *A-Du* and *Ara* for "times," as in *Ara-1* 18, for " $1\times 18=18$," *Ara-2* 36 for " $2\times 18=36$ "; the *Ara* was used also in "squaring," as in 3 *Ara* 3 9 for " $3\times 3=9$." They had the ideogram *Ba-Di-E* for "cubing," as in 27-*E* 3 *Ba-Di-E* for " $3^3=27$ "; also *Ib-Di* for "square," as in 9-*E* 3 *Ib-Di* for " $3^2=9$." The sign *A-An* rendered numbers "distributive."¹

EGYPTIANS

16. The Egyptian number system is based on the scale of 10, although traces of other systems, based on the scales of 5, 12, 20, and 60, are believed to have been discovered.² There are three forms of Egyptian numerals: the hieroglyphic, hieratic, and demotic. Of these the hieroglyphic has been traced back to about 3300 B.C.;³ it is found mainly on monuments of stone, wood, or metal. Out of the hieroglyphic sprang a more cursive writing known to us as hieratic. In the beginning the hieratic was simply the hieroglyphic in the rounded forms resulting from the rapid manipulation of a reed-pen as contrasted with the angular and precise shapes arising from the use of the chisel. About the eighth century B.C. the demotic evolved as a more abbreviated form of cursive writing. It was used since that time down to the beginning of the Christian Era. The important mathematical documents of ancient Egypt were written on papyrus and made use of the hieratic numerals.⁴

¹ Hilprecht, *op. cit.*, p. 23; Arno Poebel, *Grundzüge der sumerischen Grammatik* (Rostock, 1923), p. 115; B. Meissner, *op. cit.*, p. 387-89.

³ J. E. Quibell and F. W. Green, *Hierakonopolis* (London, 1900-1902), Part I, Plate 26B, who describe the victory monument of King *Ncr-mr*; the number of prisoners taken is given as 120,000, while 400,000 head of cattle and 1,422,000 goats were captured.

⁴ The evolution of the hieratic writing from the hieroglyphic is explained in G. Möller, *Hieratische Paläographie*, Vol. I, Nos. 614 ff. The demotic writing

17. The hieroglyphic symbols were | for 1, ∪ for 10, © for 100, ⌘ for 1,000, ¶ for 10,000, ⚡ for 100,000, ⚡ for 1,000,000, ∅ for 10,000,000. The symbol for 1 represents a vertical staff; that for 1,000 a lotus plant; that for 10,000 a pointing finger; that for 100,000 a burbot; that for 1,000,000 a man in astonishment, or, as more recent

FIG. 6.—Egyptian symbolism for simple fractions. (Compiled by Kurt Sethe)

19. In writing numbers, the Egyptians used the principles of addition and multiplication. In applying the additive principle, not more than four symbols of the same kind were placed in any one group. Thus, 4 was written in hieroglyphs $||||$; 5 was not written $|||||$, but either $||||$ or $||||$. There is here recognized the same need which caused the Romans to write V after IIII, L=50 after XXXX=40, D=500 after CCCC=400. In case of two unequal groups, the Egyptians always wrote the larger group before, or above the smaller group; thus, seven was written $||||$
 $|||$.

20. In the *older* hieroglyphs 2,000 or 3,000 was represented by two or three lotus plants grown *in one bush*. For example, 2,000 was ; correspondingly, 7,000 was designated by . The later hieroglyphs simply place two lotus plants together, to represent 2,000, without the appearance of springing from one and the same bush.

21. The multiplicative principle is not so old as the additive; it came into use about 1600–2000 B.C. In the oldest example hitherto known,¹ the symbols for 120, placed before a lotus plant, signify 120,000. A smaller number written before or below or above a symbol representing a larger unit designated multiplication of the larger by the smaller. Möller cites a case where 2,800,000 is represented by one burbot, with characters placed beneath it which stand for 28.

22. In hieroglyphic writing, unit fractions were indicated by placing the symbol  over the number representing the denominator. Exceptions to this are the modes of writing the fractions $\frac{1}{2}$ and $\frac{3}{4}$; the old hieroglyph for $\frac{1}{2}$ was , the later was ; of the slightly varying hieroglyphic forms for $\frac{3}{4}$,  was quite common.²

23. We reproduce an algebraic example in hieratic symbols, as it occurs in the most important mathematical document of antiquity known at the present time—the *Rhind papyrus*. The scribe, Ahmes, who copied this papyrus from an older document, used black and red ink, the red in the titles of the individual problems and in writing auxiliary numbers appearing in the computations. The example which, in the Eisenlohr edition of this papyrus, is numbered 34, is hereby shown.³ Hieratic writing was from right to left. To facilitate the study of the problem, we write our translation from right to left and in the same relative positions of its parts as in the papyrus, except that numbers are written in the order familiar to us; i.e., 37 is written in our translation 37, and not 73 as in the papyrus. Ahmes writes unit fractions by placing a dot over the denominator, except in case of

¹ *Ibid.*, p. 8.

² *Ibid.*, p. 92–97, gives detailed information on the forms representing $\frac{3}{4}$. The Egyptian procedure for decomposing a quotient into unit fractions is explained by V. V. Bobynin in *Abh. Gesch. Math.*, Vol. IX (1899), p. 3.

³ *Ein mathematisches Handbuch der alten Ägypter (Papyrus Rhind des British Museum) übersetzt und erklärt* (Leipzig, 1877; 2d ed., 1891). The explanation of Problem 34 is given on p. 55, the translation on p. 213, the facsimile reproduction on Plate XIII of the first edition. The second edition was brought out without the plates. A more recent edition of the Ahmes papyrus is due to T. Eric Peet and appears under the title *The Rhind Mathematical Papyrus*, British Museum, Nos. 10057 and 10058, Introduction, Transcription, and Commentary (London, 1923).

$\frac{1}{2}$, $\frac{1}{3}$, $\frac{2}{3}$, $\frac{1}{4}$, each of which had its own symbol. Some of the numeral symbols in Ahmes deviate somewhat from the forms given in the two preceding tables; other symbols are not given in those tables. For the reading of the example in question we give here the following symbols:

Four	—	One-fourth	×
Five	“1	Heap	⌒
Seven	2	The whole	13
One-half	∩	It gives	⌒

FIG. 7.—An algebraic equation and its solution in the Ahmes papyrus, 1700 B.C., or, according to recent authorities, 1550 B.C. (Problem 34, Plate XIII in Eisenlohr; p. 70 in Peet; in chancellor Chace's forthcoming edition, p. 76, as R. C. Archibald informs the writer.)

Translation (reading from right to left):

“10 gives it, whole its, $\frac{1}{4}$ its, $\frac{1}{2}$ its, Heap No. 34
 $\frac{1}{2}$ $\frac{1}{8}$ $\frac{1}{4}$ $\frac{1}{2}$ 1
 1 $\frac{1}{4}$ $\frac{1}{2}$ $\frac{1}{2}$ 3.
 $\frac{1}{4}$ $\frac{1}{2}$ $\frac{1}{2}$ 5 is heap the together 7 4
 $\frac{1}{4}$ $\frac{1}{2}$

Proof the of Beginning

$\frac{1}{4}$ $\frac{1}{2}$ $\frac{1}{2}$ 5
 $\frac{1}{8}$ $\frac{1}{4}$ $\frac{1}{2}$ 2 $\frac{1}{2}$
 $\frac{1}{8}$ $\frac{1}{4}$ $\frac{1}{2}$ 1 $\frac{1}{2}$
 14 gives $\frac{1}{4}$ $\frac{1}{8}$ $\frac{1}{4}$ $\frac{1}{2}$ $\frac{1}{2}$
 21 Together .7 gives $\frac{1}{4}$ 1 2 2 4 4 8”

24. Explanation:

The algebraic equation is $\frac{x}{2} + \frac{x}{4} + x = 10$

i.e., $(1 + \frac{1}{2} + \frac{1}{4})x = 10$

The solution answers the question, By what must $(1 \frac{1}{2} \frac{1}{4})$ be multiplied to yield the product 10? The four lines 2-5 contain on the right the following computation:

Twice $(1 \frac{1}{2} \frac{1}{4})$ yields $3 \frac{1}{2}$.

Four times $(1 \frac{1}{2} \frac{1}{4})$ yields 7.

One-seventh of $(1 \frac{1}{2} \frac{1}{4})$ is $\frac{1}{4}$.

1° UNITES:

- SIGNES		LETTRES NUMÉRALES coptes.	VALEUR des SIGNES.	NOMS DE NOMBRES en dialecte thébain.

0000 0000	IIII IIII	Ⲉ	8	chmoun.
000 000 000	IIII IIII I	ⲉ	9	psis.

[Continued on facing page]

[i.e., taking $(1 \frac{1}{2} \frac{1}{4})$ once, then four times, together with $\frac{1}{4}$ of it, yields only 9; there is lacking 1. The remaining computation is on the four lines 2-5, on the left. Since $\frac{1}{4}$ of $(1 \frac{1}{2} \frac{1}{4})$ yields $(\frac{1}{4} \frac{1}{4} \frac{1}{8})$ or $\frac{1}{4}$, $\frac{3}{8}$ or]

$(\frac{1}{4} \frac{1}{8})$ of $(1 \frac{1}{2} \frac{1}{4})$, yields $\frac{1}{2}$.

And the double of this, namely, $(\frac{1}{2} \frac{1}{4})$ of $(1 \frac{1}{2} \frac{1}{4})$ yields 1.

Adding together 1, 4, $\frac{1}{4}$ and $(\frac{1}{2} \frac{1}{4})$, we obtain Heap = $5 \frac{1}{2}$

$\frac{1}{4} \frac{1}{4}$ or $5 \frac{5}{4}$, the answer.

Proof.— $5 \frac{1}{2} \frac{1}{7} \frac{1}{14}$ is multiplied by $(1 \frac{1}{2} \frac{1}{4})$ and the partial products are added. In the first line of the proof we have $5 \frac{1}{2} \frac{1}{7} \frac{1}{14}$, in the second line half of it, in the third line one-fourth of it. Adding at first only the integers of the three partial products and the simpler fractions $\frac{1}{2}, \frac{1}{2}, \frac{1}{4}, \frac{1}{4}, \frac{1}{8}$, the partial sum is $9 \frac{1}{2} \frac{1}{8}$. This is $\frac{1}{4} \frac{1}{8}$ short of 10. In the fourth line of the proof (l. 9) the scribe writes the remaining fractions and, reducing them to the common denominator 56, he writes (in

red color) in the last line the numerators 8, 4, 4, 2, 2, 1 of the reduced fractions. Their sum is 21. But $\frac{21}{56} = \frac{14+7}{56} = \frac{1}{4} \frac{1}{8}$, which is the exact amount needed to make the total product 10.

A pair of legs symbolizing addition and subtraction, as found in impaired form in the Ahmes papyrus, are explained in § 200.

25. The Egyptian Coptic numerals are shown in Figure 8. They are of comparatively recent date. The hieroglyphic and hieratic are

the oldest Egyptian writing; the demotic appeared later. The Coptic writing is derived from the Greek and demotic writing, and was used by Christians in Egypt after the third century. The Coptic numeral symbols were adopted by the Mohammedans in Egypt after their conquest of that country.

26. At the present time two examples of the old Egyptian solution of problems involving what we now term "quadratic equations"¹ are known. For square root the symbol $\sqrt{}$ has been used in the modern hieroglyphic transcription, as the interpretation of writing in the two papyri; for quotient was used the symbol $\frac{\infty}{\infty}$.

PHOENICIANS AND SYRIANS

27. The Phoenicians² represented the numbers 1–9 by the respective number of vertical strokes. Ten was usually designated by a horizontal bar. The numbers 11–19 were expressed by the juxtaposition of a horizontal stroke and the required number of vertical ones.

Palmyrenische Zahlzeichen	1	2	3	4	5	6	7	8	9	10

Bedeutung	1	2	3	4	5	6	7	8	9	10

FIG. 9.—Palmyra (Syria) numerals. (From M. Cantor, *Kulturleben, etc.*, Fig. 48)

As Phoenician writing proceeded from right to left, the horizontal stroke signifying 10 was placed farthest to the right. Twenty was represented by two parallel strokes, either horizontal or inclined and sometimes connected by a cross-line as in H, or sometimes by two strokes, thus Λ . One hundred was written thus $|<|$ or thus $|>|$. Phoenician inscriptions from which these symbols are taken reach back several centuries before Christ. Symbols found in Palmyra (modern Tadmor in Syria) in the first 250 years of our era resemble somewhat the numerals below 100 just described. New in the Palmyra numer-

¹ See H. Schack-Schackenburg, "Der Berliner Papyrus 6619," *Zeitschrift für ägyptische Sprache und Altertumskunde*, Vol. XXXVIII (1900), p. 136, 138, and Vol. XL (1902), p. 65–66.

² Our account is taken from Moritz Cantor, *Vorlesungen über Geschichte der Mathematik*, Vol. I (3d ed.; Leipzig, 1907), p. 123, 124; *Mathematische Beiträge zum Kulturleben der Völker* (Halle, 1863), p. 255, 256, and Figs. 48 and 49.

als is γ for 5. Beginning with 100 the Palmyra numerals contain new forms. Placing a | to the right of the sign for 10 (see Fig. 9) signifies multiplication of 10 by 10, giving 100. Two vertical strokes || mean 10×20 , or 200; three of them, 10×30 , or 300.

28. Related to the Phoenician are numerals of Syria, found in manuscripts of the sixth and seventh centuries A.D. Their shapes and their mode of combination are shown in Figure 10. The Syrians employed also the twenty-two letters of their alphabet to represent the numbers 1–9, the tens 10–90, the hundreds 100–400. The following hundreds were indicated by juxtaposition: $500 = 400 + 100$, $600 = 400 + 200$, . . . , $900 = 400 + 400 + 100$, or else by writing respectively 50–90 and placing a dot over the letter to express that its value is to be taken tenfold. Thousands were indicated by the letters for 1–9, with a stroke annexed as a subscript. Ten thousands were expressed

FIG. 10.—Syrian numerals. (From M. Cantor, *Kulturleben*, etc., Fig. 49)

by drawing a small dash below the letters for one's and ten's. Millions were marked by the letters 1–9 with two strokes annexed as subscripts (i.e., $1,000 \times 1,000 = 1,000,000$).

HEBREWS

29. The Hebrews used their alphabet of twenty-two letters for the designation of numbers, on the decimal plan, up to 400. Figure 11 shows three forms of characters: the Samaritan, Hebrew, and Rabbinic or cursive. The Rabbinic was used by commentators of the Sacred Writings. In the Hebrew forms, at first, the hundreds from 500 to 800 were represented by juxtaposition of the sign for 400 and a second number sign. Thus, הק stood for 500, הר for 600, הש for 700, הת for 800.

30. Later the end forms of five letters of the Hebrew alphabet came to be used to represent the hundreds 500–900. The five letters representing 20, 40, 50, 80, 90, respectively, had two forms; one of

the forms occurred when the letter was a terminal letter of a word. These end forms were used as follows:

ץ	ף	ז	ם	ד
900	800	700	600	500 .

To represent thousands the Hebrews went back to the beginning of their alphabet and placed two dots over each letter. Thereby its value was magnified a thousand fold. Accordingly, ם̣ represented 1,000. Thus any number less than a million could be represented by their system.

31. As indicated above, the Hebrews wrote from right to left. Hence, in writing numbers, the numeral of highest value appeared on the right; ם̣ד̣ meant 5,001, ד̣ם̣ meant 1,005. But 1,005 could be written also ד̣ם̣, where the two dots were omitted, for when ם̣ meant unity, it was always placed to the left of another numeral. Hence when appearing on the right it was interpreted as meaning 1,000. With a similar understanding for other signs, one observes here the beginning of an imperfect application in Hebrew notation of the principle of local value. By about the eighth century A.D., one finds that the signs ד̣ה̣ב̣מ̣ signify 5,845, the number of verses in the laws as given in the Masora. Here the sign on the extreme right means 5,000; the next to the left is an 8 and must stand for a value less than 5,000, yet greater than the third sign representing 40. Hence the sign for 8 is taken here as 800.¹

GREEKS

32. On the island of Crete, near Greece, there developed, under Egyptian influence, a remarkable civilization. Hieroglyphic writing on clay, of perhaps about 1500 B.C., discloses number symbols as follows: ∪ or | for 1, ∪∪∪∪ or |||| or $\begin{smallmatrix} ||| \\ || \end{smallmatrix}$ for 5, • for 10, \ or / for 100, ◇ for 1,000, V for $\frac{1}{4}$ (probably), \\\\::::∪∪∪ for 483.² In this combination of symbols only the additive principle is employed. Somewhat later,³ 10 is represented also by a horizontal dash; the

¹ G. H. F. Nesselmann, *Die Algebra der Griechen* (Berlin, 1842), p. 72, 494; M. Cantor, *Vorlesungen über Geschichte der Mathematik*, Vol. I (3d ed.), p. 126, 127.

³ Arthur J. Evans, *The Palace of Minos* (London, 1921). Vol. I. p. 646; see also p. 279.

sloping line indicative of 100 and the lozenge-shaped figure used for 1,000 were replaced by the forms \bigcirc for 100, and \diamond for 1,000.

$\diamond \bigcirc \bigcirc \equiv \equiv \equiv \parallel \parallel \parallel$ stood for 2,496 .

33. The oldest strictly Greek numeral symbols were the so-called *Herodianic signs*, named after Herodianus, a Byzantine grammarian of about 200 A.D., who describes them. These signs occur frequently in Athenian inscriptions and are, on that account, now generally called Attic. They were the initial letters of numeral adjectives.¹ They were used as early as the time of Solon, about 600 B.C., and continued in use for several centuries, traces of them being found as late as the time of Cicero. From about 470 to 350 B.C. this system existed in competition with a newer one to be described presently. The Herodianic signs were

I Iota for 1	H Eta for 100
Π or Ψ or Π Pi for 5	X Chi for 1,000
Δ Delta for 10	M My for 10,000

34. Combinations of the symbols for 5 with the symbols for 10, 100, 1,000 yielded symbols for 50, 500, 5,000. These signs appear on an abacus found in 1847, represented upon a Greek marble monument on the island of Salamis.² This computing table is represented in Figure 12.

The four right-hand signs I C T X, appearing on the horizontal line below, stand for the fractions $\frac{1}{6}$, $\frac{1}{12}$, $\frac{1}{24}$, $\frac{1}{48}$, respectively. Proceeding next from right to left, we have the symbols for 1, 5, 10, 50, 100, 500, 1,000, 5,000, and finally the sign T for 6,000. The group of symbols drawn on the left margin, and that drawn above, do not contain the two symbols for 5,000 and 6,000. The pebbles in the columns represent the number 9,823. The four columns represented by the five vertical lines on the right were used for the representation of the fractional values $\frac{1}{6}$, $\frac{1}{12}$, $\frac{1}{24}$, $\frac{1}{48}$, respectively.

35. Figure 13 shows the old Herodianic numerals in an Athenian state record of the fifth century B.C. The last two lines are: *Κεφάλαιον*

ἀνα[λώατος] οὐ ἐπὶ τ[ης] ἀρχῆς ΗΗΗϞ ΤΤΤ . . . ; i.e., "Total of expenditures during our office three hundred and fifty-three talents. . . ."

36. The exact reason for the displacement of the Herodianic symbols by others is not known. It has been suggested that the commercial intercourse of Greeks with the Phoenicians, Syrians, and Hebrews brought about the change. The Phoenicians made one important contribution to civilization by their invention of the alphabet. The Babylonians and Egyptians had used their symbols to represent whole syllables or words. The Phoenicians borrowed hieratic

FIG. 12.—The computing table of Salamis

signs from Egypt and assigned them a more primitive function as letters. But the Phoenicians did not use their alphabet for numerical purposes. As previously seen, they represented numbers by vertical and horizontal bars. The earliest use of an entire alphabet for designating numbers has been attributed to the Hebrews. As previously noted, the Syrians had an alphabet representing numbers. The Greeks are supposed by some to have copied the idea from the Hebrews. But Moritz Cantor¹ argues that the Greek use is the older and that the invention of alphabetic numerals must be ascribed to the Greeks. They used the twenty-four letters of their alphabet, together with three strange and antique letters, Ϛ (old *van*), ϙ (*koppa*), ϗ (*sampi*), and the symbol M. This change was decidedly for the worse, for the old Attic numerals were less burdensome on the memory inas-

¹ *Vorlesungen über Geschichte der Mathematik*, Vol. I (3d ed., 1907), p. 25.

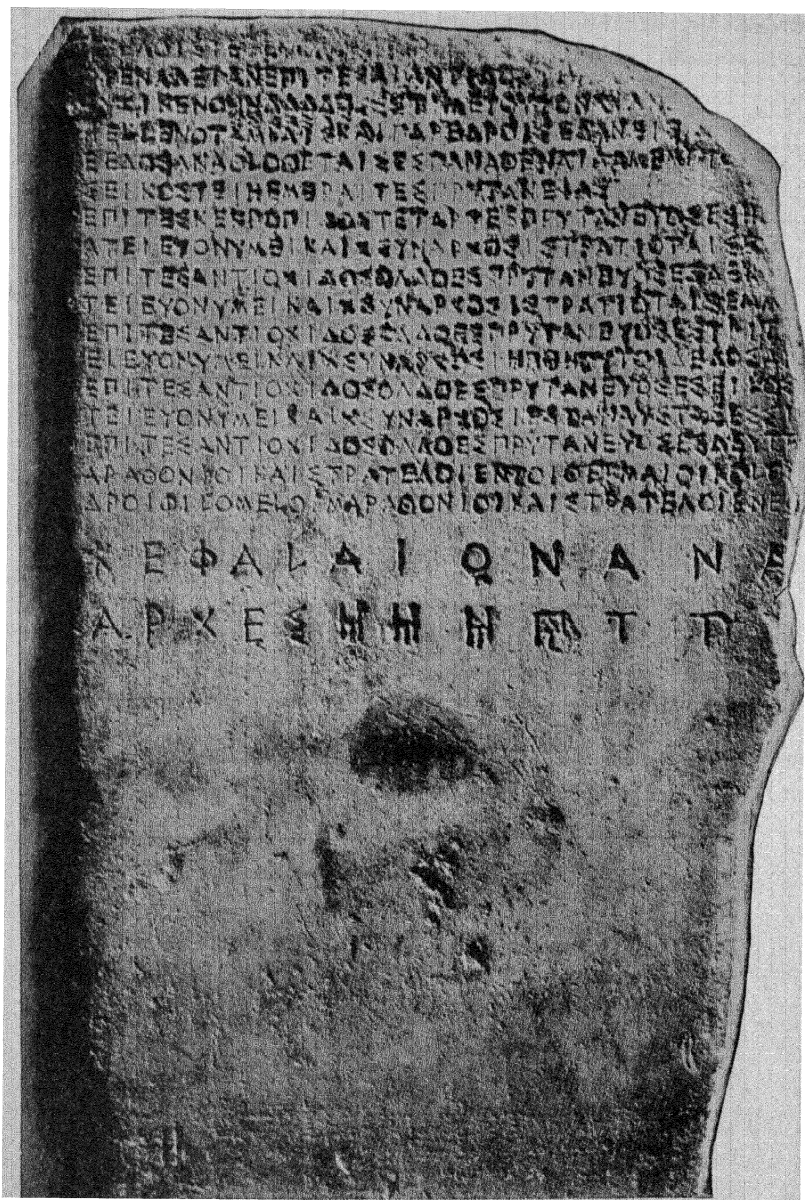

FIG. 13.—Account of disbursements of the Athenian state, 418–415 B.C., British Museum, Greek Inscription No. 23. (Taken from R. Brown, *A History of Accounting and Accountants* [Edinburgh, 1905], p. 26.)

of remembering such an array of signs was comparatively great. We are reminded of the centipede having so many legs that it could hardly advance.

39. We have here an instructive illustration of the fact that a mathematical topic may have an amount of symbolism that is a hindrance rather than a help, that becomes burdensome, that obstructs progress. We have here an early exhibition of the truth that the movements of science are not always in a forward direction. Had the Greeks not possessed an abacus and a finger symbolism, by the aid of which computations could be carried out independently of the numeral notation in vogue, their accomplishment in arithmetic and algebra might have been less than it actually was.

40. Notwithstanding the defects of the Greek system of numeral notation, its use is occasionally encountered long after far better systems were generally known. A Calabrian monk by the name of Barlaam,¹ of the early part of the fourteenth century, wrote several mathematical books in Greek, including arithmetical proofs of the second book of Euclid's *Elements*, and six books of *Logistic*, printed in 1564 at Strassburg and in several later editions. In the *Logistic* he develops the computation with integers, ordinary fractions, and sexagesimal fractions; numbers are expressed by Greek letters. The appearance of an arithmetical book using the Greek numerals at as late a period as the close of the sixteenth century in the cities of Strassburg and Paris is indeed surprising.

41. Greek writers often express fractional values in words. Thus Archimedes says that the length of a circle amounts to three diameters and a part of one, the size of which lies between one-seventh and ten-seventy-firsts.² Eratosthenes expresses $\frac{1}{3}$ of a unit arc of the earth's meridian by stating that the distance in question "amounts to eleven parts of which the meridian has eighty-three."³ When expressed in symbols, fractions were often denoted by first writing the numerator marked with an accent, then the denominator marked with two accents and written twice. Thus,⁴ $\iota\acute{\varsigma}' \kappa\alpha'' \kappa\alpha'' = \frac{1}{2}\frac{1}{7}$. Archimedes, Eutocius, and Diophantus place the denominator in the position of the

¹ All our information on Barlaam is drawn from M. Cantor, *Vorlesungen über Geschichte der Mathematik*, Vol. I (3d ed.), p. 509, 510; A. G. Kästner, *Geschichte der Mathematik* (Göttingen, 1796), Vol. I, p. 45; J. C. Heilbronner, *Historia matheseos universae* (Lipsiae, 1742), p. 488, 489.

³ Ptolemäus, *Μεγάλη σφύραξις* (ed. Heiberg), Pars I, Lib. 1, Cap. 12, p. 68.

⁴ Heron, *Stereometrica* (ed. Hultsch; Berlin, 1864), Pars I, Par. 8, p. 155.

modern exponent; thus¹ Archimedes and Eutocius use the notation

$\overline{\iota}\xi^{\kappa\alpha'}$ or $\iota\xi^{\kappa\alpha}$ for $\frac{1}{2}7$, and Diophantus (§§ 101-6), in expressing large numbers, writes (*Arithmetica*, Vol. IV, p. 17), $\frac{\beta_1\psi\delta}{\gamma\cdot\varsigma\chi\kappa\alpha} \sim$ for $\frac{36,621}{2,704}$.

Here the sign \sim takes the place of the accent. Greek writers, even as late as the Middle Ages, display a preference for unit fractions, which played a dominating rôle in old Egyptian arithmetic.² In expressing such fractions, the Greeks omitted the α' for the numerator and wrote the denominator only once. Thus $\mu\delta'' = \frac{1}{4}$. Unit fractions in juxtaposition were added,³ as in $\zeta'' \kappa\eta'' \rho\iota\beta'' \sigma\kappa\delta'' = \frac{1}{7} + \frac{1}{28} + \frac{1}{12} + \frac{1}{24}$. One finds also a single accent,⁴ as in $\delta' = \frac{1}{4}$. Frequent use of unit fractions is found in Geminus (first century B.C.), Diophantus (third century A.D.), Eutocius and Proclus (fifth century A.D.). The fraction $\frac{1}{2}$ had a mark of its own,⁵ namely, \mathcal{L} or \mathcal{L}' , but this designation was no more adopted generally among the Greeks than were the other notations of fractions. Ptolemy⁶ wrote $38^\circ 50'$ (i.e., $38^\circ \frac{1}{2} \frac{1}{3}$) thus, $\lambda\eta' \mathcal{L}'\gamma'''$. Hultsch has found in manuscripts other symbols for $\frac{1}{2}$, namely, the semicircles \frown , \smile , and the sign \mathcal{S} ; the origin of the latter is uncertain. He found also a symbol for $\frac{2}{3}$, resembling somewhat the small omega (ω).⁷ Whether these symbols represent late practice, but not early usage, it is difficult to determine with certainty.

42. A table for reducing certain ordinary fractions to the sum of unit fractions is found in a Greek papyrus from Egypt, described by

¹ G. H. F. Nesselmann, *Algebra der Griechen* (Berlin, 1842), p. 114.

² J. Baillet describes a papyrus, "Le papyrus mathématique d'Akhmîm," in *Mémoires publiés par les membres de la Mission archéologique française au Caire* (Paris, 1892), Vol. IX, p. 1-89 (8 plates). This papyrus, found at Akhmîm, in Egypt, is written in Greek, and is supposed to belong to the period between 500 and 800 A.D. It contains a table for the conversion of ordinary fractions into unit fractions.

⁷ *Metrologicorum scriptorum reliquiae* (Leipzig, 1864), Vol. I, p. 173, 174. On p. 175 and 176 Hultsch collects the numeral symbols found in three Parisian manuscripts, written in Greek, which exhibit minute variations in the symbolism. For instance, 700 is found to be ψ^π , ψ , ψ' .

L. C. Karpinski,¹ and supposed to be intermediate between the Ahmes papyrus and the Akhmim papyrus. Karpinski (p. 22) says: "In the table no distinction is made between integers and the corresponding unit fractions; thus γ' may represent either 3 or $\frac{1}{3}$, and actually $\gamma'\gamma'$ in the table represents $3\frac{1}{3}$. Commonly the letters used as numerals were distinguished in early Greek manuscripts by a bar placed above the letters but not in this manuscript nor in the Akhmim papyrus." In a third document dealing with unit fractions, a Byzantine table of fractions, described by Herbert Thompson,² $\frac{2}{3}$ is written $\bar{\iota}$; $\frac{1}{2}$, $\bar{\epsilon}$; $\frac{1}{3}$, $\bar{\nu}$ (from $\bar{\iota}'$); $\frac{1}{4}$, $\bar{\Delta}$ (from Δ'); $\frac{1}{5}$, $\bar{\epsilon}'$ (from ϵ'); $\frac{1}{6}$, $\bar{\omega}$ (from H'). As late as the fourteenth century, Nicolas Rhabdas of Smyrna wrote two letters in the Greek language, on arithmetic, containing tables for unit fractions.³ Here letters of the Greek alphabet used as integral numbers have bars placed above them.

43. About the second century before Christ the Babylonian sexagesimal numbers were in use in Greek astronomy; the letter omicron, which closely resembles in form our modern zero, was used to designate a vacant space in the writing of numbers. The Byzantines wrote it usually \bar{o} , the bar indicating a numeral significance as it has when placed over the ordinary Greek letters used as numerals.⁴

44. The division of the circle into 360 equal parts is found in Hypsicles.⁵ Hipparchus employed sexagesimal fractions regularly, as did also C. Ptolemy⁶ who, in his *Almagest*, took the approximate value of π to be $3 + \frac{8}{60} + \frac{30}{60 \times 60}$. In the Heiberg edition this value is written $\bar{\gamma} \bar{\eta} \bar{\lambda}$, purely a notation of position. In the tables, as printed by Heiberg, the dash over the letters expressing numbers is omitted. In the edition of N. Halma⁷ is given the notation $\bar{\gamma} \eta' \lambda''$, which is

³ The letters were edited by Paul Tannery in *Notices et extraits des manuscrits de la Bibliothèque Nationale*, Vol. XXXII, Part 1 (1886), p. 121-252.

⁴ C. Ptolemy, *Almagest* (ed. N. Halma; Paris, 1813), Book I, chap. ix, p. 38 and later; J. L. Heiberg, in his edition of the *Almagest* (*Synlaxis mathematica*) (Leipzig, 1898; 2d ed., Leipzig, 1903), Book I, does not write the bar over the \circ but places it over all the significant Greek numerals. This procedure has the advantage of distinguishing between the \circ which stands for 70 and the \circ which stands for zero. See *Encyc. des scien. math.*, Tome I, Vol. I (1904), p. 17, n. 89.

⁵ *Διαφορικὸς* (ed. K. Manitius), p. xxvi.

⁶ *Synlaxis mathematica* (ed. Heiberg), Vol. I, Part 1, p. 513.

probably the older form. Sexagesimal fractions were used during the whole of the Middle Ages in India, and in Arabic and Christian countries. One encounters them again in the sixteenth and seventeenth centuries. Not only sexagesimal fractions, but also the sexagesimal notation of integers, are explained by John Wallis in his *Mathesis universalis* (Oxford, 1657), page 68, and by V. Wing in his *Astronomia Britannica* (London, 1652, 1669), Book I.

EARLY ARABS

45. At the time of Mohammed the Arabs had a script which did not differ materially from that of later centuries. The letters of the early Arabic alphabet came to be used as numerals among the Arabs

1 ا	10 ی	100 ق	1000 غ	10 000 یغ	100 000 قغ
2 ب	20 ک	200 ر	2000 یغ	20 000 کغ	200 000 رغ
3 ج	30 ل	300 ش	3000 جغ	30 000 لغ	300 000 شغ
4 د	40 م	400 ت	4000 دغ	40 000 مغ	400 000 تغ
5 ه	50 ن	500 ث	5000 هغ	50 000 نغ	500 000 ثغ
6 و	60 س	600 خ	6000 و غ	60 000 سغ	600 000 خغ
7 ز	70 ع	700 ذ	7000 زغ	70 000 عغ	700 000 ذغ
8 ح	80 ف	800 ص	8000 حغ	80 000 فغ	800 000 صغ
9 ط	90 ص	900 ط	9000 طغ	90 000 صغ	900 000 طغ

FIG. 14.—Arabic alphabetic numerals used before the introduction of the Hindu-Arabic numerals.

as early as the sixth century of our era.¹ After the time of Mohammed, the conquering Moslem armies coming in contact with Greek culture acquired the Greek numerals. Administrators and military leaders used them. A tax record of the eighth century contains numbers expressed by Arabic letters and also by Greek letters.² Figure 14 is a table given by Ruska, exhibiting the Arabic letters and the numerical values which they represent. Taking the symbol for 1,000 twice, on the multiplicative principle, yielded 1,000,000. The Hindu-Arabic

² *Ibid.*, p. 49.

numerals, with the zero, began to spread among the Arabs in the ninth and tenth centuries, and they slowly displaced the Arabic and Greek numerals.¹

ROMANS

46. We possess little definite information on the origin of the Roman notation of numbers. The Romans never used the successive letters of their alphabet for numeral purposes in the manner practiced by the Syrians, Hebrews, and Greeks, although (as we shall see) an alphabet system was at one time proposed by a late Roman writer. Before the ascendancy of Rome the Etruscans, who inhabited the country nearly corresponding to modern Tuscany and who ruled Rome until about 500 B.C., used numeral signs which resembled letters of their alphabet and also resembled the numeral signs used by the Romans. Moritz Cantor² gives the Etrurian and the old Roman signs as follows: For 5, the Etrurian Λ or V , the old Roman V ; for 10 the Etrurian X or $+$, the old Roman X ; for 50 the Etrurian \uparrow or \downarrow , the old Roman \uparrow or \downarrow or \perp or \bot or L ; for 100 the Etrurian \oplus , the old Roman \ominus ; for 1,000 the Etrurian g , the old Roman \odot . The resemblance of the Etrurian numerals to Etrurian letters of the alphabet is seen from the following letters: V , $+$, \downarrow , O , 8 . These resemblances cannot be pronounced accidental. "Accidental, on the other hand," says Cantor, "appears the relationship with the later Roman signs, V , X , L , C , M , which from their resemblance to letters transformed themselves by popular etymology into these very letters." The origin of the Roman symbols for 100 and 1,000 are uncertain; those for 5 and 500 are generally admitted to be the result of a bisection of the two former. "There was close at hand," says G. Friedlein,³ "the abbreviation of the word *centum* and *mille* which at an early age brought about for 100 the sign C , and for 1,000 the sign M and after Augustus M ." A view held by some Latinists⁴ is that "the signs for 50, 100, 1,000 were originally the three Greek aspirate letters which the Romans did not require, viz., Ψ , \odot , \odot , i.e., χ , θ , Φ . The Ψ was written \perp and abbreviated into L ; \odot from a false notion of its origin made like

⁵ Ritschl, *Rhein. Mus.*, Vol. XXIV (1869), p. 12.

the initial of centum; and \textcircled{D} assimilated to ordinary letters CIC . The half of \textcircled{D} , viz., D , was taken to be $\frac{1}{2}$ 1,000, i.e., 500; X probably from the ancient form of \ominus , viz., \otimes , being adopted for 10, the half of it V was taken for 5.”¹

47. Our lack of positive information on the origin and early history of the Roman numerals is not due to a failure to advance working hypotheses. In fact, the imagination of historians has been unusually active in this field.² The dominating feature in the Roman notation is the principle of addition, as seen in II , XII , CC , MDC , etc.

48. Conspicuous also is the frequent use of the principle of subtraction. If a letter is placed before another of greater value, its value is to be subtracted from that of the greater. One sees this in IV , IX , XL . Occasionally one encounters this principle in the Babylonian notations. Remarks on the use of it are made by Adriano Cappelli in the following passage:

“The well-known rule that a smaller number, placed to the left of a larger, shall be subtracted from the latter, as $\textcircled{D}|\text{C}\text{C}=4,000$, etc., was seldom applied by the old Romans and during the entire Middle Ages one finds only a few instances of it. The cases that I have found belong to the middle of the fifteenth century and are all cases of IX , never of IV , and occurring more especially in French and Piedmontese documents. Walther, in his *Lexicon diplomaticum*, Göttingen, 1745–47, finds the notation $\text{LXL}=90$ in use in the eighth century. On the other hand one finds, conversely, the numbers IIIX , VIX with the meaning of 13 and 16, in order to conserve, as Lupi remarks, the Latin terms *tertio decimo* and *sexto decimo*.”³ L. C. Karpinski points out that the subtractive principle is found on some early tombstones and on a signboard of 130 B.C., where at the crowded end of a line 83 is written XXCIII , instead of LXXXIII .

² Consult, for example, Friedlein, *op. cit.*, p. 26–31; Nesselmann, *op. cit.*, p. 86–92; Cantor, *Mathematische Beiträge zum Kulturleben der Völker*, p. 155–67; J. C. Heilbronner, *Historia Matheseos universae* (Lipsiae, 1742), p. 732–35; Grotefend, *Lateinische Grammatik* (3d ed.; Frankfurt, 1820), Vol. II, p. 163, is quoted in the article “Zahlzeichen” in G. S. Klügel’s *Mathematisches Wörterbuch*, continued by C. B. Mollweide and J. A. Grunert (Leipzig, 1831); Mommsen, *Hermes*, Vol. XXII (1887), p. 596; Vol. XXIII (1888), p. 152. A recent discussion of the history of the Roman numerals is found in an article by Ettore Bortolotti in *Bolletino della Matheis* (Pavia, 1918), p. 60–66, which is rich in bibliographical references, as is also an article by David Eugene Smith in *Scientia* (July–August, 1926).

³ *Lexicon Abbreviaturarum* (Leipzig, 1901), p. xlix.

49. Alexander von Humboldt¹ makes the following observations:

"Summations by juxtaposition one finds everywhere among the Etruscans, Romans, Mexicans and Egyptians; subtraction or lessening forms of speech in Sanskrit among the Indians: in 19 or *unavinsati*; 99 *unusata*; among the Romans in *undeviginti* for 19 (*unus de viginti*), *undeoctoginta* for 79; *duo de quadraginta* for 38; among the Greeks *eikosi deonta henos* 19, and *pentekonta duoïn deontoin* 48, i.e., 2 missing in 50. This lessening form of speech has passed over in the graphics of numbers when the group signs for 5, 10 and even their multiples, for example, 50 or 100, are placed to the left of the characters they modify (IV and IA, XL and XT for 4 and 40) among the Romans and Etruscans (Otfried Müller, *Etrusker*, II, 317–20), although among the latter, according to Otfried Müller's new researches, the numerals descended probably entirely from the alphabet. In rare Roman inscriptions which Marini has collected (*Iscrizioni della Villa di Albano*, p. 193; Hervás, *Aritmetica delle nazioni* [1786], p. 11, 16), one finds even 4 units placed before 10, for example, IIIIX for 6."

50. There are also sporadic occurrences in the Roman notations of the principle of multiplication, according to which VM does not stand for 1,000–5, but for 5,000. Thus, in Pliny's *Historia naturalis* (about 77 A.D.), VII, 26; XXXIII, 3; IV praef., one finds² LXXXIII.M, XCII.M, CX.M for 83,000, 92,000, 110,000, respectively.

51. The thousand-fold value of a number was indicated in some instances by a horizontal line placed above it. Thus, Aelius Lampridius (fourth century A.D.) says in one place, "CXX̄, equitum Persarum fudimus: et mox X̄ in bello interemimus," where the numbers designate 120,000 and 10,000. Strokes placed on top and also on the sides indicated hundred thousands; e.g., |X̄|CLXXXDC stood for 1,180,600. In more recent practice the strokes sometimes occur only on the sides, as in |X| · DC.XC., the date on the title-page of Sigüenza's *Libra astronomica*, published in the city of Mexico in 1690. In antiquity, to prevent fraudulent alterations, XXXM was written for 30,000, and later still C|C took the place of M.³ According to

¹ "Über die bei verschiedenen Völkern üblichen Systeme von Zahlzeichen, etc.," *Crelle's Journal für die reine und angewandte Mathematik* (Berlin, 1829), Vol. IV, p. 210, 211.

² Nesselmann, *op. cit.*, p. 90.

³ Confer, on this point, Theodor Mommsen and J. Marquardt, *Manuel des antiquités romaines* (trans. G. Humbert), Vol. X by J. Marquardt (trans. A. Vigié; Paris, 1888), p. 47, 49.

Cappelli¹ "one finds, often in French documents of the Middle Ages, the multiplication of 20 expressed by two small *x*'s which are placed as exponents to the numerals III, VI, VIII, etc., as in III^{xx}=80, VI^{xx}XI=131."

52. A Spanish writer² quotes from a manuscript for the year 1392 the following:

M C
"IIII, IIII, LXXIII florins" for 4,473 florins.

M XX
"III C IIII III florins" for 3,183 (?) florins.

In a Dutch arithmetic, printed in 1771, one finds³

c c m c
i rxiij for 123, i rxiij iij lvi for 123,456.

53. For 1,000 the Romans had not only the symbol M, but also I, ∞ and C|O. According to Priscian, the celebrated Latin grammarian of about 500 A.D., the ∞ was the ancient Greek sign X for 1,000, but modified by connecting the sides by curved lines so as to distinguish it from the Roman X for 10. As late as 1593 the ∞ is used by C. Dasypodius⁴ the designer of the famous clock in the cathedral at Strasbourg. The C|O was a | inclosed in parentheses (or *apostrophos*). When only the right-hand parenthesis is written, |O, the value represented is only half, i.e., 500. According to Priscian,⁵ "quinque milia per I et duas in dextera parte apostrophos, |O. decem milia per supra dictam formam additis in sinistra parte contrariis duabus notis quam sunt apostrophos, CC|O." Accordingly, |O stood for 5,000, CC|O for 10,000; also |OO represented 50,000; and CCC|OO, 100,000; (∞), 1,000,000. If we may trust Priscian, the symbols that look like the letters C, or those letters facing in the opposite direction, were not really letters C, but were apostrophes or what we have called

⁵ "De figuris numerorum," *Henrici Keilii Grammatici Latini* (Lipsiae, 1859), Vol. III, 2, p. 407.

parentheses. Through Priscian it is established that this notation is at least as old as 500 A.D.; probably it was much older, but it was not widely used before the Middle Ages.

54. While the Hindu-Arabic numerals became generally known in Europe about 1275, the Roman numerals continued to hold a commanding place. For example, the fourteenth-century banking-house of Peruzzi in Florence—Compagnia Peruzzi—did not use Arabic numerals in their account-books. Roman numerals were used, but the larger amounts, the thousands of *lira*, were written out in words; one finds, for instance, “lb. quindicimilia CXV / V ↯ VI in fiorini” for 15,115 *lira* 5 *soldi* 6 *denari*; the specification being made that the *lira* are *lira a fiorino d'oro* at 20 *soldi* and 12 *denari*. There appears also a symbol much like γ , for thousand.¹

Nagl states also: “Specially characteristic is . . . during all the Middle Ages, the regular prolongation of the last I in the units, as VII=VII|, which had no other purpose than to prevent the subsequent addition of a further unit.”

55. In a book by H. Giraua Tarragones² at Milan the Roman numerals appear in the running text and are usually underlined; in the title-page, the date has the horizontal line *above* the numerals. The Roman four is IIII. In the tables, columns of degrees and minutes are headed “G.M.”; of hour and minutes, “H.M.” In the tables, the Hindu-Arabic numerals appear; the five is printed 5, without the usual upper stroke. The vitality of the Roman notation is illustrated further by a German writer, Sebastian Frank, of the sixteenth century, who uses Roman numerals in numbering the folios of his book and in his statistics: “Zimmet kumpt von Zailon .CC.VÑ LX. teütscher meil von Calicut weyter gelegen. . . . Die Nägelin kummen von Meluza / für Calicut hinaussgelegen vij·c. vnd XL. deutscher meyl.”³ The two numbers given are 260 and 740 German miles. Peculiar is the insertion of *vnd* (“and”). Observe also the use of the principle of multiplication in vij·c. (=700). In Jakob Köbel’s *Rechenbiechlin* (Augsburg, 1514), fractions appear in Roman numerals; thus, $\frac{II^C}{IIII^C} \cdot LX$ stands for $\frac{200}{4000} \cdot 60$.

¹ Alfred Nagl, *Zeitschrift für Mathematik und Physik*, Vol. XXXIV (1889), Historisch-literarische Abtheilung, p. 164.

³ *Weltbüch / spiegel vnd bildtnis des gantzen Erdtbodens . . . von Sebastiano Franco Wördensi . . .* (M.D. XXXIII), fol. ccxx.

56. In certain sixteenth-century Portuguese manuscripts on navigation one finds the small letter *b* used for 5, and the capital letter *R* for 40. Thus, *xbiiij* stands for 18, *Riiij* for 43.¹

FIG. 15.—Degenerate forms of Roman numerals in English archives (Common Pleas, Plea Rolls, 637, 701, and 817; also Recovery Roll 1). (Reduced.)

A curious development found in the archives of one or two English courts of the fifteenth and sixteenth centuries² was a special Roman

¹ J. I. de Brito Rebello, *Livro de Marinharia* (Lisboa, 1903), p. 37, 85–91, 193, 194.

² *Antiquaries Journal* (London, 1926), Vol. VI, p. 273, 274.

numeration for the membranes of their Rolls, the numerals assuming a degraded form which in its later stages is practically unreadable. In Figure 15 the first three forms show the number 147 as it was written in the years 1421, 1436, and 1466; the fourth form shows the number 47 as it was written in 1583.

57. At the present time the Roman notation is still widely used in marking the faces of watches and clocks, in marking the dates of books on title-pages, in numbering chapters of books, and on other occasions calling for a double numeration in which confusion might arise from the use of the same set of numerals for both. Often the Roman numerals are employed for aesthetic reasons.

58. A striking feature in Roman arithmetic is the partiality for duodecimal fractions. Why duodecimals and not decimals? We can only guess at the answer. In everyday affairs the division of units into two, three, four, and six equal parts is the commonest, and duodecimal fractions give easier expressions for these parts. Nothing definite is known regarding the time and place or the manner of the origin of these fractions. Unlike the Greeks, the Romans dealt with concrete fractions. The Roman *as*, originally a copper coin weighing one pound, was divided into 12 *unciae*. The abstract fraction $\frac{1}{12}$ was called *deuna* (= *de uncia*, i.e., *as* [1] less *uncia* [$\frac{1}{12}$]). Each duodecimal subdivision had its own name and symbol. This is shown in the following table, taken from Friedlein,¹ in which *S* stands for *semis* or "half" of an *as*.

TABLE

as.	1
deunx.	$\frac{1}{12}$	$S = -$ or $S ::$	(de uncia $1 - \frac{1}{12}$)
dextans } (decunx) }	$\frac{5}{6}$	$S =$ or $S ::$	{ (de sextans $1 - \frac{1}{6}$) (decem unciae)
dodrans.	$\frac{3}{4}$	$S =$ or $S = 1$ or $S ::$	(de quadrans $1 - \frac{1}{4}$)
bes.	$\frac{2}{3}$	$S =$ or $- S$ or $S:$	(duae assis sc. partes)
septunx.	$\frac{7}{12}$	$S -$ or $S \cdot$	(septem unciae)
semis.	$\frac{1}{2}$	S
quincunx.	$\frac{5}{12}$	$= =$ or $= -$ or $= ::$	(quinque unciae)
triens.	$\frac{1}{3}$	$= =$ or $\sum \sum$ or $::$
quadrans.	$\frac{1}{4}$	$= -$ or $= 1$ or $::$
sextans.	$\frac{1}{6}$	$=$ or Z or $:$
seuncia $1\frac{1}{2}$	$1\frac{1}{2} = \frac{3}{2}$	$- \frac{1}{2} \frac{1}{2} \frac{1}{2} \frac{1}{2}$
uncia.	$\frac{1}{12}$	$-$ or \cdot or on bronze abacus \ominus

In place of straight lines $-$ occur also curved ones \sim .

¹ *Op. cit.*, Plate 2, No. 13; see also p. 35.

59. Not all of these names and signs were used to the same extent. Since $\frac{1}{2} + \frac{1}{3} = \frac{5}{6}$, there was used in ordinary life $\frac{1}{2}$ and $\frac{1}{3}$ (*semis et triens*) in place of $\frac{5}{6}$ or $\frac{1}{2}\frac{1}{3}$ (*decunx*). Nor did the Romans confine themselves to the duodecimal fractions or their simplified equivalents $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, $\frac{1}{6}$, etc., but used, for instance, $\frac{1}{10}$ in measuring silver, a *libella* being $\frac{1}{10}$ *denarius*. The *uncia* was divided in 4 *sicilici*, and in 24 *scripuli* etc.¹ In the *Geometry* of Boethius the Roman symbols are omitted and letters of the alphabet are used to represent fractions. Very probably this part of the book is not due to Boethius, but is an interpolation by a writer of later date.

60. There are indeed indications that the Romans on rare occasions used letters for the expression of integral numbers.² Theodor Mommsen and others discovered in manuscripts found in Bern, Einsiedeln, and Vienna instances of numbers denoted by letters. Tartaglia gives in his *General trattato di numeri*, Part I (1556), folios 4, 5, the following:

A	500	I	1	R	80
B	300	K	51	S	70
C	100	L	50	T	160
D	500	M	1,000	V	5
E	250	N	90	X	10
F	40	O	11	Y	150
G	400	P	400	Z	2,000
H	200	Q	500		

61. Gerbert (Pope Sylvestre II) and his pupils explained the Roman fractions. As reproduced by Olleris,³ Gerbert's symbol for $\frac{1}{2}$ does not resemble the capital letter S, but rather the small letter ζ .

¹ For additional details and some other symbols used by the Romans, consult Friedlein, p. 33-46 and Plate 3; also H. Hankel, *op. cit.*, p. 57-61, where computations with fractions are explained. Consult also Fr. Hultsch, *Metrologic. scriptores Romani* (Leipzig, 1866).

² Friedlein, *op. cit.*, p. 20, 21, who gives references. In the *Standard Dictionary of the English Language* (New York, 1896), under S, it is stated that S stood for 7 or 70.

³ *Œuvres de Gerbert* (Paris, 1867), p. 343-48, 393-96, 583, 584.

PERUVIAN AND NORTH AMERICAN KNOT RECORDS¹
ANCIENT *QUIPU*

62. "The use of knots in cords for the purpose of reckoning, and recording numbers" was practiced by the Chinese and some other ancient people; it had a most remarkable development among the Inca of Peru, in South America, who inhabited a territory as large as the United States east of the Rocky Mountains, and were a people of superior mentality. The period of Inca supremacy extended from about the eleventh century A.D. to the time of the Spanish conquest in the sixteenth century. The *quipu* was a twisted woolen cord, upon which other smaller cords of different colors were tied. The color, length, and number of knots on them and the distance of one from another all had their significance. Specimens of these ancient *quipu* have been dug from graves.

63. We reproduce from a work by L. Leland Locke a photograph of one of the most highly developed *quipu*, along with a line diagram of the two right-hand groups of strands. In each group the top strand usually gives the sum of the numbers on the four pendent strands. Thus in the last group, the four hanging strands indicate the numbers 89, 258, 273, 38, respectively. Their sum is 658; it is recorded by the top string. The repetition of units is usually expressed by a long knot formed by tying the overhand knot and passing the cord through the loop of the knot as many times as there are units to be denoted. The numbers were expressed on the decimal plan, but the *quipu* were not adopted for calculation; pebbles and grains of maize were used in computing.

64. Nordenskiöld shows that, in Peru, 7 was a magic number; for in some *quipu*, the sums of numbers on cords of the same color, or the numbers emerging from certain other combinations, are multiples of 7 or yield groups of figures, such as 2777, 777, etc. The *quipu* disclose also astronomical knowledge of the Peruvian Indians.²

65. Dr. Leslie Spier, of the University of Washington, sends me the following facts relating to Indians in North America: "The data that I have on the *quipu*-like string records of North-American Indians indicate that there are two types. One is a long cord with knots and

¹ The data on Peru knot records given here are drawn from a most interesting work, *The Ancient Quipu or Peruvian Knot Record*, by L. Leland Locke (American Museum of Natural History, 1923). Our photographs are from the frontispiece and from the diagram facing p. 16. See Figs. 16 and 17.

² Erland Nordenskiöld, *Comparative Ethnographical Studies*, No. 6, Part 1 (1925), p. 36.

bearing beads, etc., to indicate the days. It is simply a string record. This is known from the Yakima of eastern Washington and some Interior Salish group of Nicola Valley,¹ B.C.

FIG. 16.—A *quipu*, from ancient Chancay in Peru, now kept in the American Museum of Natural History (Museum No. B8713) in New York City.

¹ J. D. Leechman and M. R. Harrington, *String Records of the Northwest, Indian Notes and Monographs* (1921).

"The other type I have seen in use among the Havasupai and Walapai of Arizona. This is a cord bearing a number of knots to indicate the days until a ceremony, etc. This is sent with the messenger who carries the invitation. A knot is cut off or untied for each day that elapses; the last one indicating the night of the dance. This is also

FIG. 17.—Diagram of the two right-hand groups of strands in Fig. 16.

used by the Northern and Southern Maidu and the Miwok of California.¹ There is a mythical reference to these among the Zuni of New Mexico.² There is a note on its appearance in San Juan Pueblo in the same state in the seventeenth century, which would indicate that its use was widely known among the Pueblo Indians. 'They directed him (the leader of the Pueblo rebellion of 1680) to make a rope of the palm leaf and tie in it a number of knots to represent the number of days before the rebellion was to take place; that he must send the rope to all the Pueblos in the Kingdom, when each should signify its approval of, and union with, the conspiracy by untying one of the knots.'³ The Huichol of Central Mexico also have knotted strings to keep count of days, untying them as the days elapse.

They also keep records of their lovers in the same way.⁴ The Zuni also keep records of days worked in this fashion.⁵

⁴ K. Lumholtz, *Unknown Mexico*, Vol. II, p. 218-30.

⁵ Leechman and Harrington, *op. cit.*

"Bourke¹ refers to medicine cords with olivella shells attached among the Tonto and Chiricahua Apache of Arizona and the Zuñi. This may be a related form.

"I think that there can be no question the instances of the second type are historically related. Whether the Yakima and Nicola Valley usage is connected with these is not established."

AZTECS

66. "For figures, one of the numerical signs was the dot (·), which marked the units, and which was repeated either up to 20 or up to the figure 10, represented by a lozenge. The number 20 was represented by a flag, which, repeated five times, gave the number 100, which was

FIG. 18.—Aztec numerals

marked by drawing quarter of the barbs of a feather. Half the barbs was equivalent to 200, three-fourths to 300, the entire feather to 400. Four hundred multiplied by the figure 20 gave 8,000, which had a purse for its symbol."² The symbols were as shown in the first line of Figure 18.

The symbols for 20, 400, and 8,000 disclose the number 20 as the base of Aztec numeration; in the juxtaposition of symbols the additive principle is employed. This is seen in the second line³ of Figure 18, which represents

$$2 \times 8,000 + 400 + 3 \times 20 + 3 \times 5 + 3 = 16,478.$$

67. The number systems of the Indian tribes of North America, while disclosing no use of a symbol for zero nor of the principle of

FIG. 19.—From the Dresden Codex, of the Maya, displaying numbers. The second column on the left, from above down, displays the numbers 9, 9, 16, 0, 0, which stand for $9 \times 144,000 + 9 \times 7,200 + 16 \times 360 + 0 + 0 = 1,366,560$. In the third column are the numerals 9, 9, 9, 16, 0, representing 1,364,360. The original appears in black and red colors. (Taken from Morley, *An Introduction to the Study of the Maya Hieroglyphs*, p. 266.)

local value, are of interest as exhibiting not only quinary, decimal, and vigesimal systems, but also ternary, quaternary, and octonary systems.¹

MAYA

68. The Maya of Central America and Southern Mexico developed hieroglyphic writing, as found on inscriptions and codices, dating apparently from about the beginning of the Christian Era, which discloses the use of a remarkable number system and chronology.² The number system discloses the application of the principle of local value, and the use of a symbol for zero centuries before the Hindus began to use their symbol for zero. The Maya system was vigesimal, except in one step. That is, 20 units (*kins*, or "days") make 1 unit of the next higher order (*uinals*, or 20 days), 18 *uinals* make 1 unit of the third order (*tun*, or 360 days), 20 *tuns* make 1 unit of the fourth order (*Katun*, or 7,200 days), 20 *Katuns* make 1 unit of the fifth order (*cycle*, or 144,000 days), and finally 20 *cycles* make 1 *great cycle* of 2,880,000 days. In the Maya codices we find symbols for 1-19, expressed by bars and dots. Each bar stands for 5 units, each dot for 1 unit. For instance,

$$\begin{array}{ccccccc} \cdot & \ddot{\cdot} & \ddot{\cdot} & \overline{} & \ddot{\cdot} & \overset{\cdot}{\overline{}} & \overset{\cdot\cdot\cdot}{\overline{\overline{}}} \\ 1 & 2 & 4 & 5 & 7 & 11 & 19 \end{array}.$$

The zero is represented by a symbol that looks roughly like a half-closed eye. In writing 20 the principle of local value enters. It is expressed by a dot placed over the symbol for zero. The numbers are written vertically, the lowest order being assigned the lowest position (see Fig. 19). The largest number found in the codices is 12,489,781.

CHINA AND JAPAN

69. According to tradition, the oldest Chinese representation of number was by the aid of *knots in strings*, such as are found later among the early inhabitants of Peru. There are extant two Chinese tablets³ exhibiting knots representing numbers, odd numbers being designated by white knots (standing for the complete, as day, warmth,

¹ W. C. Eells, "Number-Systems of North-American Indians," *American Mathematical Monthly*, Vol. XX (1913), p. 263-72, 293-99; also *Bibliotheca mathematica* (3d series, 1913), Vol. XIII, p. 218-22.

² Our information is drawn from S. G. Morley, *An Introduction to the Study of the Maya Hieroglyphs* (Washington, 1915).

³ Paul Perny, *Grammaire de la langue chinoise orale et écrite* (Paris, 1876), Vol. II, p. 5-7; Cantor, *Vorlesungen über Geschichte der Mathematik*, Vol. I (3d ed.), p. 674.

the sun) while even numbers are designated by black knots (standing for the incomplete, as night, cold, water, earth). The left-hand tablet shown in Figure 20 represents the numbers 1–10. The right-hand tablet pictures the magic square of nine cells in which the sum of each row, column, and diagonal is 15.

70. The Chinese are known to have used three other systems of writing numbers, the Old Chinese numerals, the mercantile numerals, and what have been designated as scientific numerals. The time of the introduction of each of these systems is uncertain.

FIG. 20.—Early Chinese knots in strings, representing numerals

71. The *Old Chinese numerals* were written vertically, from above down. Figure 21 shows the Old Chinese numerals and mercantile numerals, also the Japanese cursive numerals.¹

72. The *Chinese scientific numerals* are made up of vertical and horizontal rods according to the following plan: The numbers 1–9 are represented by the rods |, ||, |||, ||||, |||||, \top , Π , \equiv , \equiv ; the numbers 10–90 are written thus $_ = \equiv \equiv \equiv \equiv \perp _ = \equiv \equiv$. According to the Chinese author Sun-Tsu, units are represented, as just shown, by vertical rods, ten's by horizontal rods, hundred's again by vertical rods, and so on. For example, the number 6,728 was designated by $\perp \Pi = \equiv$.

73. The Japanese make use of the Old Chinese numerals, but have two series of names for the numeral symbols, one indigenous, the other derived from the Chinese language, as seen in Figure 21.

whole book¹ of 125 pages to the early numerals in Europe alone. Yet even Hill feels constrained to remark: "What is now offered, in the shape of just 1,000 classified examples, is nothing more than a *vinde-*

¹ *The Development of Arabic Numerals in Europe* (exhibited in 64 tables; Oxford, 1915).

miatio prima." Add to the Hill collection the numeral forms, or supposedly numeral forms, gathered from other than European sources, and the material would fill a volume very much larger than that of Hill. We are compelled, therefore, to confine ourselves to a few of the more important and interesting forms of our numerals.¹

75. One feels the more inclined to insert here only a few tables of numeral forms because the detailed and minute study of these forms has thus far been somewhat barren of positive results. With all the painstaking study which has been given to the history of our numerals we are at the present time obliged to admit that we have not even settled the time and place of their origin. At the beginning of the present century the Hindu origin of our numerals was supposed to have been established beyond reasonable doubt. But at the present time several earnest students of this perplexing question have expressed grave doubts on this point. Three investigators—G. R. Kaye in India, Carra de Vaux in France, and Nicol. Bubnov in Russia—working independently of one another, have denied the Hindu origin.² However, their arguments are far from conclusive, and the hypothesis of the Hindu origin of our numerals seems to the present writer to explain the known facts more satisfactorily than any of the substitute hypotheses thus far advanced.³

¹ The reader who desires fuller information will consult Hill's book which is very rich in bibliographical references, or David Eugene Smith and Louis Charles Karpinski's *The Hindu-Arabic Numerals* (Boston and London, 1911). See also an article on numerals in English archives by H. Jenkinson in *Antiquaries Journal*, Vol. VI (1926), p. 263-75. The valuable original researches due to F. Woepeke should be consulted, particularly his great "Mémoire sur la propagation des chiffres indiens" published in the *Journal asiatique* (6th series; Paris, 1863), p. 27-79, 234-90, 442-529. Reference should be made also to a few other publications of older date, such as G. Friedlein's *Zahlzeichen und das elementare Rechnen der Griechen und Römer* (Erlangen, 1869), which touches questions relating to our numerals. The reader will consult with profit the well-known histories of mathematics by H. Hankel and by Moritz Cantor.

76. Early Hindu mathematicians, Aryabhata (b. 476 A.D.) and Brahmagupta (b. 598 A.D.), do not give the expected information about the Hindu-Arabic numerals.

Āryabhaṭa's work, called *Aryabhaṭīya*, is composed of three parts, in only the first of which use is made of a special notation of numbers. It is an alphabetical system¹ in which the twenty-five consonants represent 1–25, respectively; other letters stand for 30, 40, . . . , 100, etc.² The other mathematical parts of Āryabhaṭa consists of rules without examples. Another alphabetic system prevailed in Southern India, the numbers 1–19 being designated by consonants, etc.³

In Brahmagupta's *Pulverizer*, as translated into English by H. T. Colebrooke,⁴ numbers are written in our notation with a zero and the principle of local value. But the manuscript of Brahmagupta used by Colebrooke belongs to a late century. The earliest commentary on Brahmagupta belongs to the tenth century; Colebrooke's text is later.⁵ Hence this manuscript cannot be accepted as evidence that Brahmagupta himself used the zero and the principle of local value.

77. Nor do inscriptions, coins, and other manuscripts throw light on the origin of our numerals. Of the old notations the most important is the Brahmi notation which did not observe place value and in which 1, 2, and 3 are represented by $_$, $=$, \equiv . The forms of the Brahmi numbers do not resemble the forms in early place-value notations⁶ of the Hindu-Arabic numerals.

Still earlier is the Kharoshthi script,⁷ used about the beginning of the Christian Era in Northwest India and Central Asia. In it the first three numbers are $|$ $||$ $|||$, then $\chi=4$, $|\chi=5$, $||\chi=6$, $\chi\chi=8$, $\gamma=10$, $3=20$, $33=40$, $\gamma33=50$, $\chi|=100$. The writing proceeds from right to left.

78. *Principle of local value.*—Until recently the preponderance of authority favored the hypothesis that our numeral system, with its concept of local value and our symbol for zero, was wholly of Hindu origin. But it is now conclusively established that the principle of

¹ M. Cantor, *Vorlesungen über Geschichte der Mathematik*, Vol. I (3d ed.), p. 606.

⁷ *Ibid.*

local value was used by the Babylonians much earlier than by the Hindus, and that the Maya of Central America used this principle and symbols for zero in a well-developed numeral system of their own and at a period antedating the Hindu use of the zero (§ 68).

79. The earliest-known reference to Hindu numerals outside of India is the one due to Bishop Severus Sebokht of Nisibis, who, living in the convent of Kenneshre on the Euphrates, refers to them in a fragment of a manuscript (MS Syriac [Paris], No. 346) of the year 662 A.D. Whether the numerals referred to are the ancestors of the modern numerals, and whether his Hindu numerals embodied the principle of local value, cannot at present be determined. Apparently hurt by the arrogance of certain Greek scholars who disparaged the Syrians, Sebokht, in the course of his remarks on astronomy and mathematics, refers to the Hindus, "their valuable methods of calculation; and their computing that surpasses description. I wish only to say that this computation is done by means of nine signs."¹

80. Some interest attaches to the earliest dates indicating the use of the perfected Hindu numerals. That some kind of numerals with a zero was used in India earlier than the ninth century is indicated by Brahmagupta (b. 598 A.D.), who gives rules for computing with a zero.² G. Bühler³ believes he has found definite mention of the decimal system and zero in the year 620 A.D. These statements do not necessarily imply the use of a decimal system based on the principle of local value. G. R. Kaye⁴ points out that the task of the antiquarian is complicated by the existence of forgeries. In the eleventh century in India "there occurred a specially great opportunity to regain confiscated endowments and to acquire fresh ones." Of seventeen citations of inscriptions before the tenth century displaying the use of place value in writing numbers, all but two are eliminated as forgeries; these two are for the years 813 and 867 A.D.; Kaye is not sure of the reliability even of these. According to D. E. Smith and L. C. Karpinski,⁵ the earliest authentic document unmistakably containing the numerals with the zero in India belongs to the year 876 A.D. The earli-

the date 349 A.H. (=961 A.D.). The oldest definitely dated European manuscript known to contain the Hindu-Arabic numerals is the Codex Vigilanus (see Fig. 22, No. 1), written in the Albelda Cloister in Spain in 976 A.D. The nine characters without the zero are given, as an addition, in a Spanish copy of the *Origines* by Isidorus of Seville, 992 A.D. A tenth-century manuscript with forms differing materially from those in the Codex Vigilanus was found in the St. Gall manuscript (see Fig. 22, No. 2), now in the University Library at Zürich. [The numerals are contained in a Vatican manuscript of 1077 (see Fig. 22, No. 3), on a Sicilian coin of 1138, in a Regensburg (Bavaria)

FIG. 23.—Table of important numeral forms. (The first six lines in this table are copied from a table at the end of Cantor's *Vorlesungen über Geschichte der Mathematik*, Vol. I. The numerals in the Bamberg arithmetic are taken from Friedrich Unger, *Die Methodik der praktischen Arithmetik in historischer Entwicklung* [Leipzig, 1888], p. 39.)

chronicle of 1197. The earliest manuscript in French giving the numerals dates about 1275. In the British Museum one English manuscript is of about 1230–50; another is of 1246. The earliest undoubted Hindu-Arabic numerals on a gravestone are at Pforzheim in Baden of 1371 and one at Ulm of 1388. The earliest coins outside of Italy that are dated in the Arabic numerals are as follows: Swiss 1424, Austrian 1484, French 1485, German 1489, Scotch 1539, English 1551.

81. *Forms of numerals.*—The Sanskrit letters of the second century A.D. head the list of symbols in the table shown in Figure 23. The implication is that the numerals have evolved from these letters. If such a connection could be really established, the Hindu origin of our numeral forms would be proved. However, a comparison of the forms appearing in that table will convince most observers that an origin

from Sanskrit letters cannot be successfully demonstrated in that way; the resemblance is no closer than it is to many other alphabets.

The forms of the numerals varied considerably. The 5 was the most freakish. An upright 7 was rare in the earlier centuries. The symbol for zero first used by the Hindus was a dot.¹ The symbol for zero (0) of the twelfth and thirteenth centuries is sometimes crossed by a horizontal line, or a line slanting upward.² The Boethian apices, as found in some manuscripts, contain a triangle inscribed in the circular zero. In Athelard of Bath's translation of Al-Madjriti's revision of Al-Khowarizmi's astronomical tables there are in different manuscripts three signs for zero,³ namely, the \ominus (=theta?) referred to above, then ρ (=teca),⁴ and $\bar{0}$. In one of the manuscripts 38 is written several times XXXO, and 28 is written XXO, the O being intended most likely as the abbreviation for *octo* ("eight").

82. The symbol τ for zero is found also in a twelfth-century manuscript⁵ of N. Ocreatus, addressed to his master Athelard. In that century it appears especially in astronomical tables as an abbreviation for *teca*, which, as already noted, was one of several names for zero;⁶ it is found in those tables by itself, without connection with other numerals. The symbol occurs in the *Algorismus vulgaris* ascribed to Sacrobosco.⁷ C. A. Nallino found \bar{o} for zero in a manuscript of Escorial, used in the preparation of an edition of Al-Battani. The symbol \ominus for zero occurs also in printed mathematical books.

The one author who in numerous writings habitually used θ for zero was the French mathematician Michael Rolle (1652-1719). One finds it in his *Traité d'algebre* (1690) and in numerous articles in the publications of the French Academy and in the *Journal des sçavans*.

Manuscripts of the fifteenth century, on arithmetic, kept in the Ashmolean Museum¹ at Oxford, represent the zero by a circle, crossed by a vertical stroke and resembling the Greek letter ϕ . Such forms for zero are reproduced by G. F. Hill² in many of his tables of numerals.

83. In the fifty-six philosophical treatises of the brothers Iḥwān aṣ-ṣafā (about 1000 A.D.) are shown Hindu-Arabic numerals and the corresponding Old Arabic numerals.

The forms of the Hindu-Arabic numerals, as given in Figure 24, have maintained themselves in Syria to the present time. They appear with almost identical form in an Arabic school primer, printed

FIG. 24.—In the first line are the Old Arabic numerals for 10, 9, 8, 7, 6, 5, 4, 3, 2, 1. In the second line are the Arabic names of the numerals. In the third line are the Hindu-Arabic numerals as given by the brothers Iḥwān aṣ-ṣafā. (Reproduced from J. Ruska, *op. cit.*, p. 87.)

at Beirut (Syria) in 1920. The only variation is in the 4, which in 1920 assumes more the form of a small Greek epsilon. Observe that 0 is represented by a dot, and 5 by a small circle. The forms used in modern Arabic schoolbooks cannot be recognized by one familiar only with the forms used in Europe.

84. In fifteenth-century Byzantine manuscripts, now kept in the Vienna Library,³ the numerals used are the Greek letters, but the principle of local value is adopted. Zero is γ or in some places \cdot ; $\alpha\alpha$ means 11, $\beta\gamma$ means 20, $\alpha\gamma\gamma\gamma$ means 1,000. "This symbol γ for zero means elsewhere 5," says Heiberg, "conversely, σ stands for 5 (as now among the Turks) in Byzantine scholia to Euclid. . . . In Constantinople the new method was for a time practiced with the retention of

³ J. L. Heiberg, "Byzantinische Analekten," *Abhandlungen zur Geschichte der Mathematik*, Vol. IX (Leipzig, 1899), p. 163, 166, 172. This manuscript in the Vienna Library is marked "Codex Phil. Gr. 65."

the old letter-numerals, mainly, no doubt, in daily intercourse." At the close of one of the Byzantine manuscripts there is a table of numerals containing an imitation of the Old Attic numerals. The table gives also the Hindu-Arabic numerals, but apparently without recognition of the principle of local value; in writing 80, the 0 is placed over the 8. This procedure is probably due to the ignorance of the scribe.

85. A manuscript¹ of the twelfth century, in Latin, contains the symbol † for 3 which Curtze and Nagl² declare to have been found only in the twelfth century. According to Curtze, the foregoing strange symbol for 3 is simply the symbol for *tertia* used in the notation for sexagesimal fractions which receive much attention in this manuscript.

86. Recently the variations in form of our numerals have been summarized as follows: "The form³ of the numerals 1, 6, 8 and 9 has not varied *much* among the [medieval] Arabs nor among the Christians of the Occident; the numerals of the Arabs of the Occident for 2, 3 and 5 have forms offering some analogy to ours (the 3 and 5 are originally reversed, as well among the Christians as among the Arabs of the Occident); but the form of 4 and that of 7 have greatly modified themselves. The numerals 5, 6, 7, 8 of the Arabs of the Orient differ distinctly from those of the Arabs of the Occident (Gobar numerals). For *five* one still writes 5 and ٥." The use of *i* for 1 occurs in the first printed arithmetic (Treviso, 1478), presumably because in this early stage of printing there was no type for 1. Thus, 9,341 was printed 934*i*.

87. Many points of historical interest are contained in the following quotations from the writings of Alexander von Humboldt. Although over a century old, they still are valuable.

"In the Gobar⁴ the group signs are dots, that is zeroes, for in India, Tibet and Persia the zeroes and dots are identical. The Gobar symbols, which since the year 1818 have commanded my whole attention, were discovered by my friend and teacher, Mr. Silvestre de Sacy, in a manuscript from the Library of the old Abbey St. Germain du Près. This great orientalist says: 'Le Gobar a un grand rapport

¹ Algorithmus-MSS Clm 13021, fols. 27-29, of the Munich Staatsbibliothek. Printed and explained by Maximilian Curtze, *Abhandlungen zur Geschichte der Mathematik*, Vol. VIII (Leipzig, 1898), p. 3-27.

⁴ Alexander von Humboldt, *Crelle's Journal*, Vol. IV (1829), p. 223, 224.

avec le chiffre indien, mais il n'a pas de zéro (S. *Gramm. arabe*, p. 76, and the note added to Pl. 8).' I am of the opinion that the zero-symbol is present, but, as in the Scholia of Neophytos on the units, it stands over the units, not by their side. Indeed it is these very zero-symbols or dots, which give these characters the singular name *Gobar* or dust-writing. At first sight one is uncertain whether one should recognize therein a transition between numerals and letters of the alphabet. One distinguishes with difficulty the Indian 3, 4, 5 and 9. *Dal* and *ha* are perhaps ill-formed Indian numerals 6 and 2. The notation by dots is as follows:

3^{\cdot} for 30 ,
 $4^{\cdot\cdot}$ for 400 ,
 $6^{\cdot\cdot}$ for 6,000 .

These dots remind one of an old-Greek but rare notation (Ducange, *Palaeogr.*, p. xii), which begins with the myriad: $\alpha^{\cdot\cdot}$ for 10,000, $\beta^{\cdot\cdot}$ for 200 millions. In this system of geometric progressions a single dot, which however is not written down, stands for 100. In Diophantus and Pappus a dot is placed between letter-numerals, instead of the initial *Mv* (myriad). A dot multiplies what lies to its left by 10,000. . . . A real zero symbol, standing for the absence of some unit, is applied by Ptolemy in the descending sexagesimal scale for missing degrees, minutes or seconds. Delambre claims to have found our symbol for zero also in manuscripts of Theon, in the Commentary to the Syntaxis of Ptolemy.¹ It is therefore much older in the Occident than the invasion of the Arabs and the work of Planudes on *arithmoi indikoi*." L. C. Karpinski² has called attention to a passage in the Arabic biographical work, the *Fihrist* (987 A.D.), which describes a Hindu notation using dots placed *below* the numerals; one dot indicates tens, two dots hundreds, and three dots thousands.

88. There are indications that the magic power of the principle of local value was not recognized in India from the beginning, and that our perfected Hindu-Arabic notation resulted from gradual evolution. Says Humboldt: "In favor of the successive perfecting of the designation of numbers in India testify the Tamul numerals which, by means

¹ J. B. J. Delambre, *Histoire de l'astron. ancienne*, Vol. I, p. 547; Vol. II, p. 10. The alleged passage in the manuscripts of Theon is not found in his printed works. Delambre is inclined to ascribe the Greek sign for zero either as an abbreviation of *ouden* or as due to the special relation of the numeral omieron to the sexagesimal fractions (*op. cit.*, Vol. II, p. 14, and *Journal des sçavans* [1817], p. 539).

² *Bibliotheca mathematica*, Vol. XI (1910-11), p. 121-24.

of the nine signs for the units and by signs of the groups 10, 100, or 1,000, express all values through the aid of multipliers placed on the

FIG. 26.—From Christoff Rudolff's *Künstliche Rechnung mit der Ziffer* (Augsburg, 1574[?]).

Library (Cod. Reg., fol. 15), for an account of which I am indebted to Prof. Brandis. The nine digits of Neophytos wholly resemble the Persian, except the 4. The digits 1, 2, 3 and 9 are found even in Egyptian number inscriptions (Kosegarten, *de Hierogl. Aegypt.*, p. 54). The nine units are enhanced tenfold, 100 fold, 1,000 fold by writing above them one, two or three zeros, as in:

$\overset{\circ}{2} = 20$, $\overset{\circ}{24} = 24$, $\overset{\circ}{5} = 500$, $\overset{\circ}{6} = 6,000$. If we imagine dots in place of the zero symbols, then we have the arabic Gobar numerals."¹ Humboldt copies the scholium of Neophytos. J. L. Heiberg also has called attention to the scholium of Neophytos and to the numbering of scholia to Euclid in a Greek manuscript of the twelfth century (Codex Vindobonensis, Gr. 103), in which numerals resembling the Gobar numerals occur.² The numerals of the monk Neophytos (Fig. 25), of which Humboldt speaks, have received the special attention of P. Tannery.³

89. *Freak forms*.—We reproduce herewith from the Augsburg edition of Christoff Rudolff's *Künstliche Rechnung* a set of our numerals, and of symbols to represent such fractions

¹ *Op. cit.*, p. 227.

² See J. L. Heiberg's edition of *Euclid* (Leipzig, 1888), Vol. V; P. Tannery, *Revue archéol.* (3d ser., 1885), Vol. V, p. 99, also (3d ser., 1886), Vol. VII, p. 355; *Encycl des scien. math.*, Tome I, Vol. I (1904), p. 20, n. 102.

³ *Mémoires scientifiques*, Vol. IV (Toulouse and Paris, 1920), p. 22.

and mixed numbers as were used in Vienna in the measurement of wine. We have not seen the first edition (1526) of Rudolff's book, but Alfred Nagl¹ reproduces part of these numerals from the first edition. "In the Viennese wine-cellars," says Hill, "the casks were marked according to their contents with figures of the forms given."² The symbols for fractions are very curious.

90. *Negative numerals.*—J. Colson³ in 1726 claimed that, by the use of negative numerals, operations may be performed with "more ease and expedition." If 8605729398715 is to be multiplied by 389175836438, reduce these to small numbers $\bar{1}\bar{4}\bar{1}\bar{4}\bar{3}\bar{3}\bar{1}\bar{4}\bar{0}\bar{1}\bar{3}\bar{1}\bar{5}$ and $4\bar{1}\bar{1}\bar{2}\bar{2}\bar{1}\bar{2}\bar{4}\bar{4}\bar{4}\bar{2}$. Then write the multiplier on a slip of paper and place it in an inverted position, so that its first figure is just over the left-hand figure of the multiplicand. Multiply $4 \times 1 = 4$ and write down 4. Move the multiplier a place to the right and collect the two products, $4 \times \bar{1} + \bar{1} \times 1 = \bar{5}$; write down $\bar{5}$. Move the multiplier another place to the right, then $4 \times \bar{4} + \bar{1} \times \bar{1} + \bar{1} \times 1 = \bar{1}\bar{6}$; write the $\bar{1}$ in the second line. Similarly, the next product is 11, and so on. Similar processes and notations were proposed by A. Cauchy,⁴ E. Selling,⁵ and W. B. Ford,⁶ while J. P. Ballantine⁷ suggests 1 inverted, thus $\bar{1}$, as a sign for negative 1, so that $1 \times 7 = 13$ and the logarithm $9.69897 - 10$ may be written 19.69897 or $\bar{1}.69897$. Negative logarithmic characteristics are often marked with a negative sign placed over the numeral (Vol. II, § 476).

91. *Grouping digits in numeration.*—In the writing of numbers containing many digits it is desirable to have some symbol separating the numbers into groups of, say, three digits. Dots, vertical bars, commas, arcs, and colons occur most frequently as signs of separation.

In a manuscript, *Liber algorizmi*,⁸ of about 1200 A.D., there appear

dots to mark periods of three. Leonardo of Pisa, in his *Liber Abbaci* (1202), directs that the hundreds, hundred thousands, hundred millions, etc., be marked with an accent above; that the thousands, millions, thousands of millions, etc., be marked with an accent below.

In the 1228 edition,¹ Leonardo writes $\overbrace{678} \overbrace{935} \overbrace{784} \overbrace{105} 296$. Johannes de Sacrobosco (d. 1256), in his *Tractatus de arte numerandi*, suggests that every third digit be marked with a dot.² His commentator, Petrus de Dacia, in the first half of the fourteenth century, does the same.³ Directions of the same sort are given by Paolo Dagomari⁴ of Florence, in his *Regoluzze di Maestro Paolo dall Abbaco* and Paolo of Pisa,⁵ both writers of the fourteenth century. Luca Pacioli, in his *Summa* (1494), folio 19b, writes 8 659 421 635 894 676; Georg Peur-

bach (1505),⁶ $\overline{\overline{3790528614}}$. Adam Riese⁷ writes $\overline{\overline{86789325178}}$. M. Stifel (1544)⁸ writes $\overline{\overline{2329089562800}}$. Gemma Frisius⁹ in 1540 wrote 24 456 345 678. Adam Riese (1535)¹⁰ writes 86 · 7 · 89 · 3 · 25 · 178. The Dutch writer, Martinus Carolus Creszfeldt,¹¹ in 1557 gives in his *Arithmetica* the following marking of a number:

“Exempel. || $\overbrace{5} \overbrace{8} \overbrace{7} \overbrace{4} \overbrace{9} \overbrace{3} \overbrace{6} \overbrace{2} \overbrace{5} \overbrace{3} \overbrace{4}$ || .”

York City is given as "3.437:202"; in a recent Spanish encyclopedia,¹ the population of America is put down as "150.979,995."

In the process of extracting square root, two early commentators² on Bhāskara's *Lilavati*, namely Rama-Crishna Deva and Gangad'hara (ca. 1420 A.D.), divide numbers into periods of two digits in this manner, $\overset{1}{8} \overset{8}{8} \overset{2}{2} \overset{0}{0} \overset{9}{9}$. In finding cube roots Rama-Crishna Deva writes $\overset{1}{1} \overset{9}{9} \overset{5}{5} \overset{3}{3} \overset{1}{1} \overset{2}{2} \overset{5}{5}$.

92. *The Spanish "calderón."*—In Old Spanish and Portuguese numeral notations there are some strange and curious symbols. In a contract written in Mexico City in 1649 the symbols "7U291e" and "VIIUCCXCips" each represent 7,291 *pesos*. The U, which here resembles an O that is open at the top, stands for "thousands."³ I. B. Richman has seen Spanish manuscripts ranging from 1587 to about 1700, and Mexican manuscripts from 1768 to 1855, all containing symbols for "thousands" resembling U or D, often crossed by one or two horizontal or vertical bars. The writer has observed that after 1600 this U is used freely both with Hindu-Arabic and with Roman numerals; *before 1600* the U occurs more commonly with Roman numerals. Karpinski has pointed out that it is used with the Hindu-Arabic numerals as early as 1519, in the accounts of the Magellan voyages. As the Roman notation does not involve the principle of local value, U played in it a somewhat larger rôle than merely to afford greater facility in the reading of numbers. Thus VIUCXV equals $6 \times 1,000 + 115$. This use is shown in manuscripts from Peru of 1549 and 1543,⁴ in manuscripts from Spain of 1480⁵ and 1429.⁶

We have seen the corresponding *type symbol* for 1,000 in Juan Perez de Moya,⁷ in accounts of the coining in the Real Casa de Moneda de

Mexico (1787), in eighteenth-century books printed in Madrid,¹ in the *Gazetas de Mexico* of 1784 (p. 1), and in modern reprints of seventeenth-century documents.² In these publications the printed symbol resembles the Greek sampi ϣ for 900, but it has no known connection with it. In books printed in Madrid³ in 1760, 1655, and 1646, the symbol is a closer imitation of the written U, and is curiously made up of the two small printed letters, *l*, *f*, each turned halfway around. The two inverted letters touch each other below, thus *lf*. Printed symbols representing a distorted U have been found also in some Spanish arithmetics of the sixteenth century, particularly in that of Gaspard de Texeda⁴ who writes the number 103,075,102,300 in the Castellanean form c.iiijU.75qs c.ijU300 and also in the algoristic form 103U075qs 102U300. The Spaniards call this symbol and also the sampi-like symbol a *calderón*.⁵ A non-Spanish author who explains the *calderón* is Johann Caramuel,⁶ in 1670.

93. The present writer has been able to follow the trail of this curious symbol U from Spain to Northwestern Italy. In Adriano Cappelli's *Lexicon* is found the following: "In the liguric documents of the second half of the fifteenth century we found in frequent use, to indicate the multiplication by 1,000, in place of M, an O crossed by a horizontal line."⁷ This closely resembles some forms of our Spanish symbol U. Cappelli gives two facsimile reproductions⁸ in

⁸ *Ibid.*, p. 436, col. 1, Nos. 5 and 6.

which the sign in question is small and is placed in the position of an exponent to the letters XL, to represent the number 40,000. This corresponds to the use of a small *c* which has been found written to the right of and above the letters XI, to signify 1,100. It follows, therefore, that the modified U was in use during the fifteenth century in Italy, as well as in Spain, though it is not known which country had the priority.

What is the origin of this *calderón*? Our studies along this line make it almost certain that it is a modification of one of the Roman

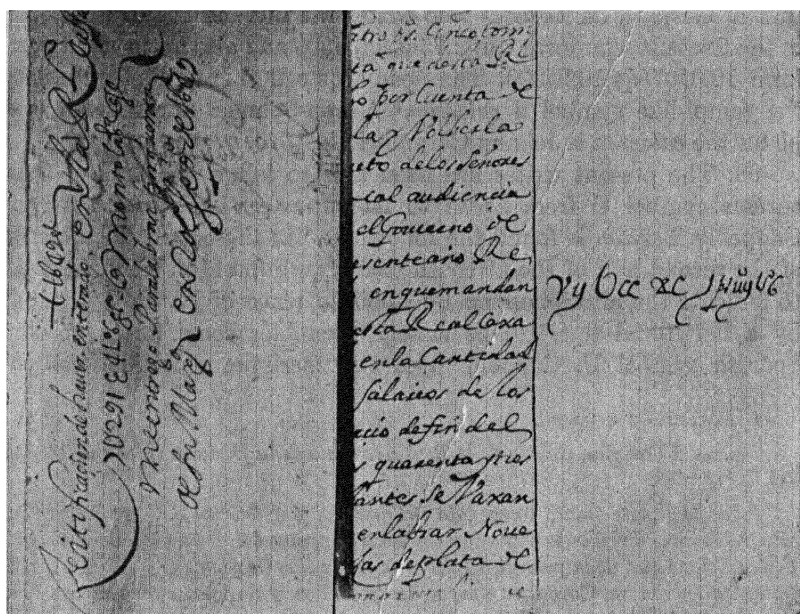

FIG. 27.—From a contract (Mexico City, 1649). The right part shows the sum of 7,291 pesos, 4 tomines, 6 granos, expressed in Roman numerals and the *calderón*. The left part, from the same contract, shows the same sum in Hindu-Arabic numerals and the *calderón*.

symbols for 1,000. Besides M, the Romans used for 1,000 the symbols CIO, T, ∞, and †. These symbols are found also in Spanish manuscripts. It is easy to see how in the hands of successive generations of amanuenses, some of these might assume the forms of the *calderón*. If the lower parts of the parentheses in the forms CIO or CIO are united, we have a close imitation of the U, crossed by one or by two bars.

94. *The Portuguese "cifrão."*—Allied to the distorted Spanish U is the Portuguese symbol for 1,000, called the *cifrão*.¹ It looks somewhat like our modern dollar mark, \$. But its function in writing numbers was identical with that of the *calderón*. Moreover, we have seen forms of this Spanish "thousand" which need only to be turned through a right angle to appear like the Portuguese symbol for 1,000. Changes of that sort are not unknown. For instance, the Arabic numeral 5 appears upside down in some Spanish books and manuscripts as late as the eighteenth and nineteenth centuries.

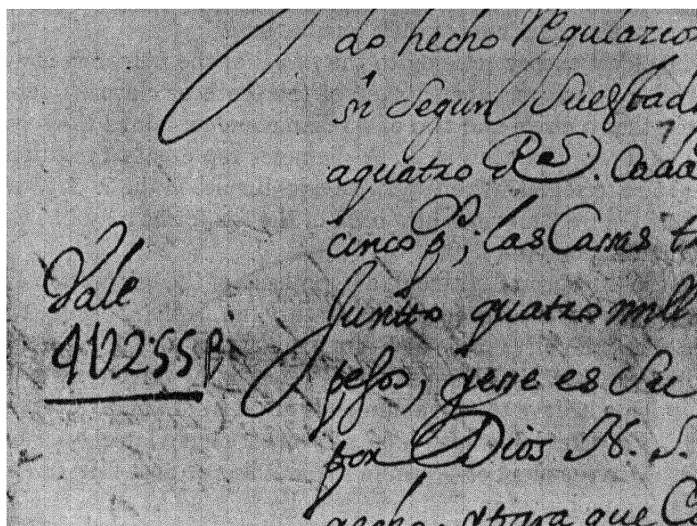

FIG. 28.—Real estate sale in Mexico City, 1718. The sum written here is 4,255 pesos.

95. *Relative size of numerals in tables.*—André says on this point: "In certain numerical tables, as those of Schrön, all numerals are of the same height. In certain other tables, as those of Lalande, of Callet, of Houël, of Dupuis, they have unequal heights: the 7 and 9 are prolonged downward; 3, 4, 5, 6 and 8 extend upward; while 1 and 2 do not reach above nor below the central body of the writing. . . . The unequal numerals, by their very inequality, render the long train of numerals easier to read; numerals of uniform height are less legible."²

¹ See the word *cifrão* in Antonio de Moraes Silva, *Dicc. de Língua Portuguesa* (1877); in Vieira, *Grande Dicc. Portuguez* (1873); in *Dicc. Comtemp. da Língua Portuguesa* (1881).

96. *Fanciful hypotheses on the origin of the numeral forms.*—A problem as fascinating as the puzzle of the origin of language relates to the evolution of the forms of our numerals. Proceeding on the traditional assumption that each of our numerals contains within itself, like a skeleton so to speak, as many dots, strokes, or angles as it represents units, imaginative writers of different countries and ages have advanced hypotheses as to their origin. Nor did these writers feel that they were indulging simply in pleasing pastime or merely contributing to mathematical recreations. With perhaps only one exception, they were as convinced of the correctness of their explanations as are circle-squarers of the soundness of their quadratures.

The oldest theory relating to the forms of the numerals is due to the Arabic astrologer Aben Ragel¹ of the tenth or eleventh century. He held that a circle and two of its diameters contained the requirements of the forms as it were in a nutshell. A diameter represents 1; a diameter and the two terminal arcs on opposite sides furnished the 2. A glance at Part I of Figure 29 reveals how each of the ten forms may be evolved from the fundamental figure.

On the European Continent, a hypothesis of the origin from dots is the earliest. In the seventeenth century an Italian Jesuit writer, Mario Bettini,² advanced such an explanation which was eagerly accepted in 1651 by Georg Philipp Harsdörffer³ in Germany, who said: "Some believe that the numerals arose from points or dots," and in Part II. The same idea was advanced much later by Georges Dumesnil⁴ in the manner shown in the first line of Part III. In our writing the points supposedly came to be written as dashes, yielding forms resembling those of the second line of Part III. The two horizontal dashes for 2 became connected by a slanting line yielding the modern form. In the same way the three horizontal dashes for 3 were joined by two slanting lines. The 4, as first drawn, resembled the 0; but confusion was avoided by moving the upper horizontal stroke into

FIG. 29.—Fanciful hypotheses

changed from a vertical to a horizontal position and placed at the top of the numeral. That all these changes were accepted as historical,

without an atom of manuscript evidence to support the different steps in the supposed evolution, is an indication that Baconian inductive methods of research had not gripped the mind of Dumesnil. The origin from dots appealed to him the more strongly because points played a rôle in Pythagorean philosophy and he assumed that our numeral system originated with the Pythagoreans.

Carlos le-Maur,¹ of Madrid, in 1778 suggested that lines joining the centers of circles (or pebbles), placed as shown in the first line of Part IV, constituted the fundamental numeral forms. The explanation is especially weak in accounting for the forms of the first three numerals.

A French writer, P. Voizot,² entertained the theory that originally a numeral contained as many angles as it represents units, as seen in Part V. He did not claim credit for this explanation, but ascribed it to a writer in the Genova Catholico Militarite. But Voizot did originate a theory of his own, based on the number of strokes, as shown in Part VI.

Edouard Lucas³ entertains readers with a legend that Solomon's ring contained a square and its diagonals, as shown in Part VII, from which the numeral figures were obtained. Lucas may have taken this explanation from Jacob Leupold⁴ who in 1727 gave it as widely current in his day.

The historian Moritz Cantor⁵ tells of an attempt by Anton Müller⁶ to explain the shapes of the digits by the number of strokes necessary to construct the forms as seen in Part VIII. An eighteenth-century writer, Georg Wachter,⁷ placed the strokes differently, somewhat as in Part IX. Cantor tells also of another writer, Piccard,⁸ who at one time had entertained the idea that the shapes were originally deter-

mined by the number of strokes, straight or curved, necessary to express the units to be denoted. The detailed execution of this idea, as shown in Part IX, is somewhat different from that of Müller and some others. But after critical examination of his hypothesis, Piccard candidly arrives at the conclusion that the resemblances he pointed out are only accidental, especially in the case of 5, 7, and 9, and that his hypothesis is not valid.

This same Piccard offered a special explanation of the forms of the numerals as found in the geometry of Boethius and known as the "Apices of Boethius." He tried to connect these forms with letters in the Phoenician and Greek alphabets (see Part X). Another writer whose explanation is not known to us was J. B. Reveillaud.¹

The historian W. W. R. Ball² in 1888 repeated with apparent approval the suggestion that the nine numerals were originally formed by drawing as many strokes as there are units represented by the respective numerals, with dotted lines added to indicate how the writing became cursive, as in Part XI. Later Ball abandoned this explanation. A slightly different attempt to build up numerals on the consideration of the number of strokes is cited by W. Lietzmann.³ A still different combination of dashes, as seen in Part XII, was made by the German, David Arnold Crusius, in 1746.⁴ Finally, C. P. Sherman⁵ explains the origin by numbers of short straight lines, as shown in Part XIII. "As time went on," he says, "writers tended more and more to substitute the easy curve for the difficult straight line and not to lift the pen from the paper between detached lines, but to join the two—which we will call cursive writing."

These hypotheses of the origin of the forms of our numerals have been barren of results. The value of any scientific hypothesis lies in co-ordinating known facts and in suggesting new inquiries likely to advance our knowledge of the subject under investigation. The hypotheses here described have done neither. They do not explain the very great variety of forms which our numerals took at different times

and in different countries. They simply endeavor to explain the numerals as they are printed in our modern European books. Nor have they suggested any fruitful new inquiry. They serve merely as entertaining illustrations of the operation of a pseudo-scientific imagination, uncontrolled by all the known facts.

97. *A sporadic artificial system.*—A most singular system of numeral symbols was described by Agrippa von Nettesheim in his *De occulta philosophia* (1531) and more fully by Jan Bronkhorst of Nijmegen in Holland who is named after his birthplace Noviomagus.¹ In 1539 he published at Cologne a tract, *De numeris*, in which he describes numerals composed of straight lines or strokes which, he claims, were used by *Chaldaei et Astrologi*. Who these Chaldeans are whom he mentions it is difficult to ascertain; Cantor conjectures that they were late Roman or medieval astrologers. The symbols are given again in a document published by M. Hostus in 1582 at Antwerp. An examination of the symbols indicates that they enable one to write numbers up into the millions in a very concise form. But this conciseness is attained at a great sacrifice of simplicity; the burden on the memory is great. It does not appear as if these numerals grew by successive steps of time; it is more likely that they are the product of some inventor who hoped, perhaps, to see his symbols supersede the older (to him) crude and clumsy contrivances.

An examination, in Figure 30, of the symbols for 1, 10, 100, and 1,000 indicates how the numerals are made up of straight lines. The same is seen in 4, 40, 400, and 4,000 or in 5, 50, 500, and 5,000.

98. *General remarks.*—Evidently one of the earliest ways of recording the small numbers, from 1 to 5, was by writing the corresponding number of strokes or bars. To shorten the record in expressing larger numbers new devices were employed, such as placing the bars representing higher values in a different position from the others, or the introduction of an altogether new symbol, to be associated with the primitive strokes on the additive, or multiplicative principle, or in some cases also on the subtractive principle.

After the introduction of alphabets, and the observing of a fixed sequence in listing the letters of the alphabets, the use of these letters

¹ See M. Cantor, *Vorlesungen über Geschichte der Mathematik*, Vol. II (2d ed.; Leipzig, 1913), p. 410; M. Cantor, *Mathemat. Beiträge zum Kulturleben der Völker* (Halle, 1863), p. 166, 167; G. Friedlein, *Die Zahlzeichen und das elementare Rechnen der Griechen und Römer* (Erlangen, 1869), p. 12; T. H. Martin, *Annali di matematica* (B. Tortolini; Rome, 1863), Vol. V, p. 298; J. C. Heilbronner, *Historia Matheseos universae* (Lipsiae, 1742), p. 735-37; J. Ruska, *Archiv für die Geschichte der Naturwissenschaften und Technik*, Vol. IX (1922), p. 112-26.

for the designation of numbers was introduced among the Syrians, Greeks, Hebrews, and the early Arabs. The alphabetic numeral systems called for only very primitive powers of invention; they made

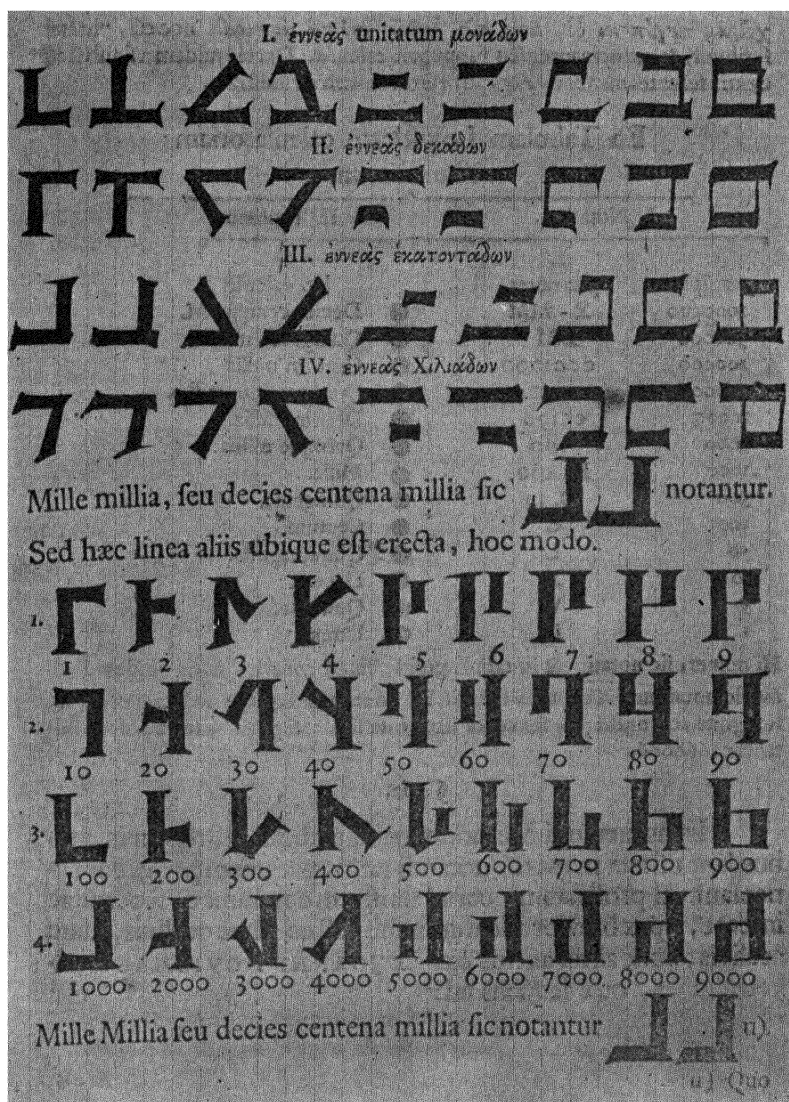

FIG. 30.—The numerals described by Noviomagus in 1539. (Taken from J. C. Heilbronner, *Historia matheseos* [1742], p. 736.)

unnecessarily heavy demands on the memory and embodied no attempt to aid in the processes of computation.

The highest powers of invention were displayed in the systems employing the principle of local value. Instead of introducing new symbols for units of higher order, this principle cleverly utilized the position of one symbol relative to others, as the means of designating different orders. Three important systems utilized this principle: the Babylonian, the Maya, and the Hindu-Arabic systems. These three were based upon different scales, namely, 60, 20 (except in one step), and 10, respectively. The principle of local value applied to a scale with a small base affords magnificent adaptation to processes of computation. Comparing the processes of multiplication and division which we carry out in the Hindu-Arabic scale with what the alphabetical systems or the Roman system afforded places the superiority of the Hindu-Arabic scale in full view. The Greeks resorted to abacal computation, which is simply a primitive way of observing local value in computation. In what way the Maya or the Babylonians used their notations in computation is not evident from records that have come down to us. The scales of 20 or 60 would call for large multiplication tables.

The origin and development of the Hindu-Arabic notation has received intensive study. Nevertheless, little is known. An outstanding fact is that during the past one thousand years no uniformity in the shapes of the numerals has been reached. An American is sometimes puzzled by the shape of the number 5 written in France. A European traveler in Turkey would find that what in Europe is a 0 is in Turkey a 5.

99. *Opinion of Laplace.*—Laplace¹ expresses his admiration for the invention of the Hindu-Arabic numerals and notation in this wise: "It is from the Indians that there has come to us the ingenious method of expressing all numbers, in ten characters, by giving them, at the same time, an absolute and a place value; an idea fine and important, which appears indeed so simple, that for this very reason we do not sufficiently recognize its merit. But this very simplicity, and the extreme facility which this method imparts to all calculation, place our system of arithmetic in the first rank of the useful inventions. How difficult it was to invent such a method one can infer from the fact that it escaped the genius of Archimedes and of Apollonius of Perga, two of the greatest men of antiquity."

¹ *Exposition du système du monde* (6th ed.; Paris, 1835), p. 376.

III

SYMBOLS IN ARITHMETIC AND ALGEBRA (ELEMENTARY PART)

100. In ancient Babylonian and Egyptian documents occur certain ideograms and symbols which are not attributable to particular individuals and are omitted here for that reason. Among these signs is \sqcap for square root, occurring in a papyrus found at Kahun and now at University College, London,¹ and a pair of walking legs for squaring in the Moscow papyrus.² These symbols and ideograms will be referred to in our "Topical Survey" of notations.

A. GROUPS OF SYMBOLS USED BY INDIVIDUAL WRITERS

GREEK: DIOPHANTUS, THIRD CENTURY A.D.

101. The unknown number in algebra, defined by Diophantus as containing an undefined number of units, is represented by the Greek letter ς with an accent, thus ς' , or in the form $\varsigma\acute{o}$. In plural cases the symbol was doubled by the Byzantines and later writers, with the addition of case endings. Paul Tannery holds that the evidence is against supposing that Diophantus himself duplicated the sign.³ G. H. F. Nesselmann⁴ takes this symbol to be final sigma and remarks that probably its selection was prompted by the fact that it was the only letter in the Greek alphabet which was not used in writing numbers. Heath favors "the assumption that the sign was a mere tachygraphic abbreviation and not an algebraical symbol like our x , though discharging much the same function."⁵ Tannery suggests that the sign is the ancient letter koppa, perhaps slightly modified. Other views on this topic are recorded by Heath.

¹ Moritz Cantor, *Vorlesungen über Geschichte der Mathematik*, Vol. I, 3d ed., Leipzig, p. 94.

² B. Touraëff, *Ancient Egypt* (1917), p. 102.

³ *Diophanti Alexandrini opera omnia cum Graecis commentariis* (Lipsiae, 1895), Vol. II, p. xxxiv–xlii; Sir Thomas L. Heath, *Diophantus of Alexandria* (2d ed.; Cambridge, 1910), p. 32, 33.

⁴ *Die Algebra der Griechen* (Berlin, 1842), p. 290, 291.

⁵ *Op. cit.*, p. 34–36.

A square, x^2 , is in Diophantus' *Arithmetica* Δ^Y

A cube, x^3 , is in Diophantus' *Arithmetica* K^Y

A square-square, x^4 , is in Diophantus' *Arithmetica* $\Delta^Y\Delta$

A square-cube, x^5 , is in Diophantus' *Arithmetica* ΔK^Y

A cube-cube, x^6 , is in Diophantus' *Arithmetica* K^YK

In place of the capital letters kappa and delta, small letters are sometimes used.¹ Heath² comments on these symbols as follows: "There is no obvious connection between the symbol Δ^Y and the symbol ς of which it is the square, as there is between x^2 and x , and in this lies the great inconvenience of the notation. But upon this notation no advance was made even by late editors, such as Xylander, or by Bachet and Fermat. They wrote N (which was short for *Numerus*) for the ς of Diophantus, Q (*Quadratus*) for Δ^Y , C (*Cubus*) for K^Y , so that we find, for example, $1Q+5N=24$, corresponding to $x^2+5x=24$.³ Other symbols were however used even before the publication of Xylander's *Diophantus*, e.g., in Bombelli's *Algebra*."

102. Diophantus has no symbol for multiplication; he writes down the numerical results of multiplication without any preliminary step which would necessitate the use of a symbol. Addition is expressed

¹ From Fermat's edition of Bachet's *Diophantus* (Toulouse, 1670), p. 2, Definition II, we quote: "Appellatur igitur Quadratus, Dynamis, & est illius nota δ superscriptum habens $\bar{\upsilon}$ sic $\delta\bar{\upsilon}$. Qui autem sit ex quadrato in suum latus cubus est, cuius nota est κ , superscriptum habens $\bar{\upsilon}$ hoc pacto $\kappa\bar{\upsilon}$. Qui autem sit ex quadrato in seipsum multiplicato, quadrato-quadratus est, cuius nota est geminum δ habens superscriptum $\bar{\upsilon}$, hac ratione $\delta\delta\bar{\upsilon}$. Qui sit quadrato in cubum qui ab eodem latere profectus est, ducto, quadrato-cubus nominatur, nota eius $\delta\kappa$ superscriptum habens $\bar{\upsilon}$ sic $\delta\kappa\bar{\upsilon}$. Qui ex cubo in se ducto nascitur, cubocubus vocatur, & est eius nota geminum κ superscriptum habens $\bar{\upsilon}$, hoc pacto $\kappa\kappa\bar{\upsilon}$. Cui vero nulla harum proprietatum obtigit, sed constat multitudine vnitatem rationis experte, numerus vocatur, nota eius ς . Est et aliud signum immutabile definitorum, vnitatis, cuius nota μ superscriptum habens $\bar{\upsilon}$ sic $\mu\bar{\upsilon}$." The passage in Bachet's edition of 1621 is the same as this.

² *Op. cit.*, p. 38.

³ In Fermat's edition of Bachet's *Diophantus* (Toulouse, 1670), p. 3, Definition II, we read: "Haec ad verbum exprimenda esse arbitratus sum potius quam cum Xilandro nescio quid aliud comminisci. Quamvis enim in reliqua versione nostra notis ab eodem Xilandro excogitatis libenter vsus sim, quas tradam infrà. Hic tamen ab ipso Diophanto longius recedere nolui, quod hac definitione notas explicet quibus passim libris istis vtitur ad species omnes compendio designandas, & qui has ignoret ne quidem Graeca Diophanti legere possit. Porrò quadratum Dynamis vocat, quae vox potestatem sonat, quia videlicet quadratus est veluti potestas cuius libet lineae, & passim ab Euclide, per id quod potest linea, quadratus illius designatur. Itali, Hispanique eadem ferè de causa Censum vocant, quasi

y mere juxtaposition. Thus the polynomial X^3+13x^2+5x+2 would be in Diophantine symbols $K^Y\bar{a}\Delta^Y\overline{\gamma}\bar{s}\bar{e}\bar{M}\bar{\beta}$, where \bar{M} is used to represent units and shows that $\bar{\beta}$ or 2 is the absolute term and not a part of the coefficient of s or x . It is to be noted that in Diophantus' "square-cube" symbol for x^5 , and "cube-cube" symbol for x^6 , the *additive* principle for exponents is employed, rather than the *multiplicative* principle (found later widely prevalent among the Arabs and Italians), according to which the "square-cube" power would mean x^6 and the "cube-cube" would mean x^9 .

103. Diophantus' symbol for subtraction is "an inverted Ψ with the top shortened, Λ ." Heath pertinently remarks: "As Diophantus used no distinct sign for $+$, it is clearly necessary, in order to avoid confusion, that all the negative terms in an expression, should be placed together after all the positive terms. And so in fact he does place them."¹ As regards the origin of this sign Λ , Heath believes that the explanation which is quoted above from the Diophantine text as we have it is not due to Diophantus himself, but is "an explanation made by a scribe of a symbol which he did not understand." Heath² advances the hypothesis that the symbol originated by placing \mid within the uncial form Λ , thus yielding Λ . Paul Tannery,³ on the other hand, in 1895 thought that the sign in question was adapted from the old letter sampi Ϡ , but in 1904 he⁴ concluded that it was rather a conventional abbreviation associated with the root of a certain Greek verb. His considerations involve questions of Greek grammar and were prompted by the appearance of the Diophantine sign

cas redditum, proeuntúmque, quòd à latere seu radice, tanquam à feraci solo
 adratu oriatur. Inde factum vt Gallorum nonnulli & Germanorum corrupto
 cabulo zenzum appellarint. Numerum autem indeterminatum & ignotum, qui

⁴ *Bibliotheca mathematica* (3d ser.), Vol. V, p. 5–8.

of subtraction in the critical notes to Schöne's edition¹ of the *Metrica* of Heron.

For equality the sign in the archetypal manuscripts seems to have been ι^{σ} ; "but copyists introduced a sign which was sometimes confused with the sign \mathfrak{u} " (Heath).

104. The notation for division comes under the same head as the notation for fractions (see § 41). In the case of unit fractions, a double accent is used with the denominator: thus $\gamma'' = \frac{1}{3}$. Sometimes a simple accent is used; sometimes it appears in a somewhat modified form as \wedge , or (as Tannery interprets it) as χ : thus $y^{\chi} = \frac{1}{3}$. For $\frac{1}{2}$ appear the symbols \angle' and \smile , the latter sometimes without the dot. Of fractions that are not unit fractions, $\frac{3}{4}$ has a peculiar sign \mathfrak{W} of its own, as was the case in Egyptian notations. "Curiously enough," says Heath, "it occurs only four times in Diophantus." In some old manuscripts the denominator is written above the numerator, in some rare cases. Once we find $\iota\epsilon^{\delta} = \frac{1}{4}^{\delta}$, the denominator taking the position where we place exponents. Another alternative is to write the numerator first and the denominator after it in the same line, marking the denominator with a submultiple sign in some form: thus, $\overline{\gamma}\delta' = \frac{3}{4}$.² The following are examples of fractions from Diophantus:

$$\text{From v. 10: } \iota\beta = \frac{17}{12}$$

$$\text{From v. 8, Lemma: } \bar{\beta}\angle's' = 2\frac{1}{2}\frac{1}{3}$$

$$\text{From iv. 3: } s\chi\bar{\eta} = \frac{8}{x}$$

$$\text{From iv. 15: } \Delta^{\gamma}\chi\overline{\sigma\nu} = \frac{250}{x^2}$$

$$\begin{aligned} \text{From vi. 12: } \Delta^{\gamma}\bar{\xi}\bar{M}, \overline{\beta\phi\kappa} \epsilon\nu \gamma\phi\iota\omega \Delta^{\gamma}\bar{\alpha}\bar{M}\mathfrak{J} \wedge \Delta^{\gamma}\bar{\xi} \\ = (60x^2 + 2,520)/(x^4 + 900 - 60x^2) . \end{aligned}$$

105. The fact that Diophantus had only one symbol for unknown quantity affected considerably his mode of exposition. Says Heath: "This limitation has made his procedure often very different from our modern work." As we have seen, Diophantus used but few symbols. Sometimes he ignored even these by describing an operation in words, when the symbol would have answered as well or better. Considering the amount of symbolism used, Diophantus' algebra may be designated as "syncopated."

¹ *Heronis Alexandrini opera*, Vol. III (Leipzig, 1903), p. 156, l. 8, 10. The manuscript reading is $\mu\omicron\nu\acute{\alpha}\delta\omega\nu \omicron\delta\tau\acute{\iota}\delta'$, the meaning of which is $74 - \frac{1}{4}$.

² Heath, *op. cit.*, p. 45, 47.

HINDU: BRAHMAGUPTA, SEVENTH CENTURY A.D.

106. We begin with a quotation from H. T. Colebrooke on Hindu algebraic notation:¹ "The Hindu algebraists use abbreviations and initials for symbols: they distinguish negative quantities by a dot, but have not any mark, besides the absence of the negative sign, to discriminate a positive quantity. No marks or symbols (other than abbreviations of words) indicating operations of addition or multiplication, etc., are employed by them: nor any announcing equality² or relative magnitude (greater or less). . . . A fraction is indicated by placing the divisor under the dividend, but without a line of separation. The two sides of an equation are ordered in the same manner, one under the other. . . . The symbols of unknown quantity are not confined to a single one: but extend to ever so great a variety of denominations: and the characters used are the initial syllables of the names of colours, excepting the first, which is the initial of *yávat-távat*, as much as."

107. In Brahmagupta,³ and later Hindu writers, abbreviations occur which, when transliterated into our alphabet, are as follows:

ru for *rupa*, the absolute number
ya for *yávat-távat*, the (first) unknown
ca for *calaca* (black), a second unknown
ní for *nílaca* (blue), a third unknown
pí for *pítaca* (yellow), a fourth unknown
pa for *pandu* (white), a fifth unknown
lo for *lohita* (red), a sixth unknown
c for *carantí*, surd, or square root
ya v for x^2 , the *v* being the contraction for
varga, square number

108. In Brahmagupta,⁴ the division of *ru* 3 *c* 450 *c* 75 *c* 54 by *c* 18 *c* 3 (i.e., $3 + \sqrt{450} + \sqrt{75} + \sqrt{54}$ by $\sqrt{18} + \sqrt{3}$) is carried out as follows: "Put *c* 18 *c* 3. The dividend and divisor, multiplied by this, make *ru* 75 *c* 625. The dividend being then divided by the single surd
ru 15

constituting the divisor, the quotient is *ru* 5 *c* 3."

¹ H. T. Colebrooke, *Algebra, with Arithmetic and Mensuration from the Sanscrit of Brahmagupta and Bhāscara* (London, 1817), p. x, xi.

² The Bakhshālī MS (§ 109) was found after the time of Colebrooke and has an equality sign.

³ *Ibid.*, p. 339 ff.

⁴ *Brahme-sphuṭa-sidd'hānta*, chap. xii. Translated by H. T. Colebrooke in *op. cit.* (1817), p. 277-378; we quote from p. 342.

A HISTORY OF MATHEMATICAL NOTATIONS

In modern symbols, the statement is, substantially: Multiplidend and divisor by $\sqrt{18}-\sqrt{3}$; the products are $75+\sqrt{675}$ and 15; divide the former by the latter, $5+\sqrt{3}$.

“Question 16.¹ When does the residue of revolutions of the sun less one, fall, on a Wednesday, equal to the square root of two less than the residue of revolutions, less one, multiplied by ten and augmented by two?

“The value of residue of revolutions is to be here put square c *yavat-ívat* with two added: *ya v 1 ru 2* is the residue of revolutions

Sanskrit character:

or letters, by which the Hindus denote the unknown quantities in their notation, are the following : पा, का, नी, पी, लो.

FIG. 31.—Sanskrit symbols for unknowns. (From Charles Hutton, *Mathematical Tracts*, II, 167.) The first symbol, *pa*, is the contraction for “white”; the second, *ca*, the initial for “black”; the third, *ni*, the initial for “blue”; the fourth, *pi*, the initial for “yellow”; the fifth, *lo*, for “red.”

This less two is *ya v 1*; the square root of which is *ya 1*. Less one, it is *ya 1 ru 1*; which multiplied by ten is *ya 10 ru 10*; and augmented by two, *ya 10 ru 8*. It is equal to the residue of revolutions *ya v 1 ru 2* less one; viz. *ya v 1 ru 1*. Statement of both sides $\frac{ya\ v\ 0\ ya\ 10\ ru\ 8}{ya\ v\ 1\ ya\ 0\ ru\ 1}$. Equa

subtraction being made conformably to rule 1 there arises $\frac{ru\ 9}{ya\ 10}$

Now, from the absolute number (9), multiplied by four times the [coefficient of the] square (36), and added to (100) the square of the [coefficient of the] middle term (making consequently 64), the square root being extracted (8), and lessened by the [coefficient of the] middle term (10), the remainder is 18 divided by twice the [coefficient of the] square (2), yields the value of the middle term 9. Substituting with this in the expression put for the residue of revolutions, the answer comes out, residue of revolutions of the sun 83. Elapsed period of days deduced from this, 393, must have the denominator in least terms added so often until it fall on Wednesday.”

¹ Colebrooke, *op. cit.*, p. 346. The abbreviations *ru*, *c*, *ya*, *ya v*, *ca*, *ni*, etc., are transliterations of the corresponding letters in the Sanskrit alphabet

Notice that $\begin{matrix} ya & v & 0 & ya & 10 & ru & \dot{8} \\ ya & v & 1 & ya & 0 & ru & 1 \end{matrix}$ signifies $0x^2 + 10x - 8 = x^2 + 0x + 1$.

Brahmagupta gives¹ the following equation in three unknown quantities and the expression of one unknown in terms of the other two:

$$\begin{matrix} "ya & 197 & ca & 1644 & nt & \dot{1} & ru & 0 \\ ya & 0 & ca & 0 & nt & 0 & ru & 6302. \end{matrix}$$

Equal subtraction being made, the value of *yávat-lávat* is

$$\begin{matrix} ca & 1644 & nt & 1 & ru & 6302. " \\ (ya) & 197 \end{matrix}$$

In modern notation:

$$197x - 1644y - z + 0 = 0x + 0y + 0z + 6302,$$

whence,

$$x = \frac{1644y + z + 6302}{197}.$$

HINDU: THE BAKHSHĀLĪ MS

109. The so-called Bakhshālī MS, found in 1881 buried in the earth near the village of Bakhshālī in the northwestern frontier of India, is an arithmetic written on leaves of birch-bark, but has come down in mutilated condition. It is an incomplete copy of an older manuscript, the copy having been prepared, probably about the eighth, ninth, or tenth century. "The system of notation," says A. F. Rudolph Hoernle,² "is much the same as that employed in the arithmetical works of Brahmagupta and Bhāskara. There is, however, a very important exception. The *sign for the negative* quantity is a cross (+). It looks exactly like our modern sign for the positive quantity, but it is placed after the number which it qualifies. Thus $12\ 7+$ means $12-7$ (i.e. 5). This is a sign which I have not met with 1 1

in any other Indian arithmetic. . . . The sign now used is a dot placed over the number to which it refers. Here, therefore, there appears to be a mark of great antiquity. As to its origin I am not able to suggest any satisfactory explanation. . . . A *whole* number, when it occurs in an arithmetical operation, as may be seen from the above given example, is indicated by placing the number 1 under it. This, however, is

¹ Colebrooke, *op. cit.*, p. 352.

² "The Bakhshālī Manuscript," *Indian Antiquary*, Vol. XVII (Bombay, 1888), p. 33-48, 275-79; see p. 34.

a practice which is still occasionally observed in India. . . . The following statement from the first example of the twenty-fifth *sūtra* affords a good example of the system of notation employed in the Bakhshālī arithmetic:

$$\left| \begin{array}{cccc} \cdot & 1 & 1 & 1 & bhā & 32 \\ \dot{1} & 1 & 1 & 1 & & \\ 3+ & 3+ & 3+ & & & \end{array} \right| \text{ phalaṁ 108}$$

Here the initial dot is used much in the same way as we use the letter x to denote the unknown quantity, the value of which is sought. The number 1 under the dot is the sign of the whole (in this case, unknown) number. A fraction is denoted by placing one number under the other without any line of separation; thus $\frac{1}{3}$ is $\frac{1}{3}$, i.e. one-third. A mixed number is shown by placing the three numbers under one another; thus $\frac{1}{3}$ is $1+\frac{1}{3}$ or $1\frac{1}{3}$, i.e. one and one-third. Hence $\frac{1}{3+}$ means $1-\frac{1}{3}$ (i.e. $\frac{2}{3}$). Multiplication is usually indicated by placing the numbers side by side; thus

$$\left| \begin{array}{cc} 5 & 32 \\ 8 & 1 \end{array} \right| \text{ phalaṁ 20}$$

means $\frac{5}{8} \times 32 = 20$. Similarly $\frac{1}{3+} \frac{1}{3+} \frac{1}{3+}$ means $\frac{2}{3} \times \frac{2}{3} \times \frac{2}{3}$ or $\left(\frac{2}{3}\right)^3$,

i.e. $\frac{8}{27}$. *Bhā* is an abbreviation of *bhāga*, 'part,' and means that the number preceding it is to be treated as a denominator. Hence

$\frac{1}{3+} \frac{1}{3+} \frac{1}{3+}$ *bhā* means $1 \div \frac{8}{27}$ or $\frac{27}{8}$. The whole statement, therefore,

$$\left| \begin{array}{cccc} \cdot & 1 & 1 & 1 & bhā & 32 \\ \dot{1} & 1 & 1 & 1 & & \\ 3+ & 3+ & 3+ & & & \end{array} \right| \text{ phalaṁ 108,}$$

means $\frac{27}{8} \times 32 = 108$, and may be thus explained,—'a certain number is found by dividing with $\frac{8}{27}$ and multiplying with 32; that number is 108.' The dot is also used for another purpose, namely as one of the

ten fundamental figures of the decimal system of notation, or the zero (0123456789). It is still so used in India for both purposes, to indicate the unknown quantity as well as the naught. . . . The Indian dot, unlike our modern zero, is not properly a numerical figure at all. It is simply a sign to indicate an empty place or a hiatus. This is clearly shown by its name *sūnya*, 'empty.' . . . Thus the two figures 3 and 7, placed in juxtaposition (37), mean 'thirty-seven,' but with an 'empty space' interposed between them (3 7), they mean 'three hundred and seven.' To

prevent misunderstanding the presence of the 'empty space' was indicated by a dot (3.7); or by what is now the zero (307). On the other hand, occurring in the statement of a problem, the 'empty place' could be filled up, and here the dot which marked its presence signified a 'something' which was to be discovered and to

be put in the empty place. . . . In its double signification, which still survives in India, we can still discern an indication of that country as its birthplace. . . . The operation of multiplication alone is not indicated by any special sign. Addition is indicated by *yu* (for *yuta*), subtraction by + (*ka* for *kanita*?) and division by *bhā* (for *bhāga*). The whole operation is commonly enclosed between lines (or sometimes double lines), and the result is set down outside, introduced by *pha* (for *phala*).'' Thus, *pha* served as a sign of equality.

The problem solved in Figure 32 appears from the extant parts to have been: Of a certain quantity of goods, a merchant has to pay, as duty, $\frac{1}{3}$, $\frac{1}{4}$, and $\frac{1}{5}$ on three successive occasions. The total duty is 24. What was the original quantity of his goods? The solution appears in the manuscript as follows: "Having subtracted the series from one," we get $\frac{2}{3}$, $\frac{3}{4}$, $\frac{4}{5}$; these multiplied together give $\frac{8}{15}$; that again, subtracted from 1 gives $\frac{7}{15}$; with this, after having divided (i.e., inverted, $\frac{15}{7}$), the total duty (24) is multiplied, giving 40; that is the original amount. Proof: $\frac{8}{15}$ multiplied by 40 gives 16 as the remainder. Hence the original amount is 40. Another proof: 40 multiplied by $1 - \frac{1}{3}$ and $1 - \frac{1}{4}$ and $1 - \frac{1}{5}$ gives the result 16; the deduction is 24; hence the total is 40.

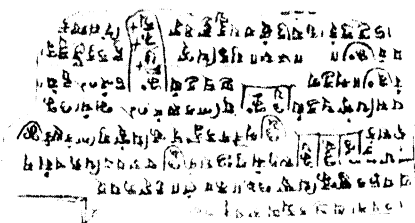

FIG. 32.—From Bakhshālī arithmetic (G. R. Kaye, *Indian Mathematics* [1915], p. 26; R. Hoernle, *op. cit.*, p. 277).

HINDU: BHĀSKARA, TWELFTH CENTURY A.D.

110. Bhāskara speaks in his *Lilavati*¹ of squares and cubes of numbers and makes an allusion to the raising of numbers to higher powers than the cube. Ganesa, a sixteenth-century Indian commentator of Bhāskara, specifies some of them. Taking the words *varga* for square of a number, and *g'hana* for cube of a number (found in Bhāskara and earlier writers), Ganesa explains² that the product of four like numbers is the square of a square, *varga-varga*; the product of six like numbers is the cube of a square, or square of a cube, *varga-g'hana* or *g'hana-varga*; the product of eight numbers gives *varga-varga-varga*; of nine, gives the cube of a cube, *g'hana-g'hana*. The fifth power was called *varga-g'hana-ghāta*; the seventh, *varga-varga-g'hana-ghāta*.

111. It is of importance to note that the higher powers of the unknown number are built up on the principle of involution, except the powers whose index is a prime number. According to this principle, indices are multiplied. Thus *g'hana-varga* does not mean $n^3 \cdot n^2 = n^5$, but $(n^3)^2 = n^6$. Similarly, *g'hana-g'hana* does not mean $n^3 \cdot n^3 = n^6$, but $(n^3)^3 = n^9$. In the case of indices that are prime, as in the fifth and seventh powers, the multiplicative principle became inoperative and the additive principle was resorted to. This is indicated by the word *ghāta* ("product"). Thus, *varga-g'hana-ghāta* means $n^2 \cdot n^3 = n^5$.

In the application, whenever possible, of the multiplicative principle in building up a symbolism for the higher powers of a number, we see a departure from Diophantus. With Diophantus the symbol for x^2 , followed by the symbol for x^3 , meant x^5 ; with the Hindus it meant x^6 . We shall see that among the Arabs and the Europeans of the thirteenth to the seventeenth centuries, the practice was divided, some following the Hindu plan, others the plan of Diophantus.

112. In Bhāskara, when unlike colors (dissimilar unknown quantities, like x and y) are multiplied together, the result is called *bhavita* ("product"), and is abbreviated *bha*. Says Colebrooke: "The product of two unknown quantities is denoted by three letters or syllables, as *ya.ca bha*, *ca.ni bha*, etc. Or, if one of the quantities be a higher power, more syllables or letters are requisite; for the square, cube, etc., are likewise denoted by the initial syllables, *va*, *gha*, *va-va*, *va-gha*, *gha-gha*,³ etc. Thus *ya va · ca gha bha* will signify the square of the

¹ Colebrooke, *op. cit.*, p. 9, 10.

² *Ibid.*, p. 10, n. 3; p. 11.

³ *Gha-gha* for the sixth, instead of the ninth, power, indicates the use here of the additive principle.

first unknown quantity multiplied by the cube of the second. A dot is, in some copies of the text and its commentaries, interposed between the factors, without any special direction, however, for this notation."¹ Instead of *ya va* one finds in Brahmagupta and Bhāskara also the severer contraction *ya v*; similarly, one finds *cav* for the square of the second unknown.²

It should be noted also that "equations are not ordered so as to put all the quantities positive; nor to give precedence to a positive term in a compound quantity: for the negative terms are retained, and even preferably put in the first place."³

According to N. Ramanujacharia and G. R. Kaye,⁴ the content of the part of the manuscript shown in Figure 33 is as follows: The

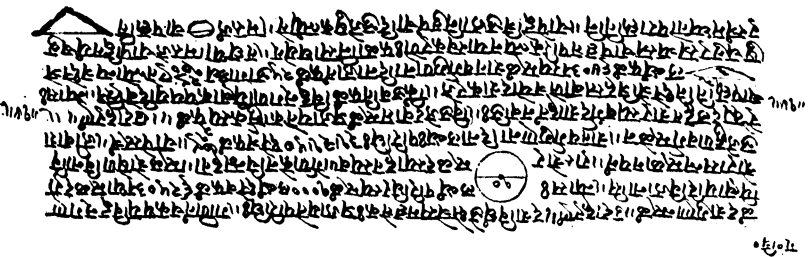

FIG. 33.—Śrīdhara's *Trisatikā*. Śrīdhara was born 991 A.D. He is cited by Bhāskara; he explains the "Hindu method of completing the square" in solving quadratic equations.

circumference of a circle is equal to the square root of ten times the square of its diameter. The area is the square root of the product of ten with the square of half the diameter. Multiply the quantity whose square root cannot be found by any large number, take the square root of the product, leaving out of account the remainder. Divide it by the square root of the factor. To find the segment of a circle, take the sum of the chord and arrow, multiply it by the arrow, and square the product. Again multiply it by ten-ninths and extract its square root. Plane figures other than these areas should be calculated by considering them to be composed of quadrilaterals, segments of circles, etc.

¹ *Op. cit.*, p. 140, n. 2; p. 141. In this quotation we omitted, for simplicity, some of the accents found in Colebrooke's transliteration from the Sanskrit.

² *Ibid.*, p. 63, 140, 346.

³ *Ibid.*, p. xii.

⁴ *Bibliotheca mathematica* (3d ser.), Vol. XIII (1912-13), p. 206, 213, 214.

113. *Bhāskara Āchārya*, "*Lilavati*,"¹ 1150 A.D.—"Example: Tell me the fractions reduced to a common denominator which answer to three and a fifth, and one-third, proposed for addition; and those which correspond to a sixty-third and a fourteenth offered for subtraction. Statement:

$$\begin{array}{r} 3 \quad 1 \quad 1 \\ 1 \quad 5 \quad 3 \end{array}$$

Answer: Reduced to a common denominator

$$\begin{array}{r} 45 \quad 3 \quad 5 \\ 15 \quad 15 \quad 15 \end{array} \quad \begin{array}{r} \text{Sum} \\ 15 \end{array}$$

Statement of the second example:

$$\begin{array}{r} 1 \quad 1 \\ 63 \quad 14 \end{array}$$

Answer: The denominator being abridged, or reduced to least terms, by the common measure seven, the fractions become

$$\begin{array}{r} 1 \quad 1 \\ 9 \quad 2 \end{array}$$

Numerator and denominator, multiplied by the abridged denominators, give respectively $\frac{2}{126}$ and $\frac{9}{126}$. Subtraction being made, the difference is $\frac{7}{126}$."

114. *Bhāskara Āchārya*, "*Vija-Ganita*."²—"Example: Tell quickly the result of the numbers three and four, negative or affirmative, taken together: . . . The characters, denoting the quantities known and unknown, should be first written to indicate them generally; and those, which become negative, should be then marked with a dot over them. Statement:³ $3 \cdot 4$. Adding them, the sum is found 7. Statement: $\dot{3} \cdot \dot{4}$. Adding them, the sum is $\dot{7}$. Statement: $3 \cdot \dot{4}$. Taking the difference, the result of addition comes out $\dot{1}$.

"'So much as' and the colours 'black, blue, yellow and red,'⁴ and others besides these, have been selected by venerable teachers for names of values of unknown quantities, for the purpose of reckoning therewith.

¹ Colebrooke, *op. cit.*, p. 13, 14.

² *Ibid.*, p. 131.

³ In modern notation, $3+4=7$, $(-3)+(-4)=-7$, $3+(-4)=-1$.

⁴ Colebrooke, *op. cit.*, p. 139.

"Example:¹ Say quickly, friend, what will affirmative one unknown with one absolute, and affirmative pair unknown less eight absolute, make, if addition of the two sets take place? Statement:²

$$\begin{array}{ll} ya & 1 \quad ru \quad 1 \\ ya & 2 \quad ru \quad \dot{8} \end{array}$$

Answer: The sum is $ya \ 3 \quad ru \ \dot{7}$.

"When absolute number and colour (or letter) are multiplied one by the other, the product will be colour (or letter). When two, three or more homogeneous quantities are multiplied together, the product will be the square, cube or other [power] of the quantity. But, if unlike quantities be multiplied, the result is their (*bhāvita*) 'to be' product or factum.

"23. Example:³ Tell directly, learned sir, the product of the multiplication of the unknown (*yāvat-tāvat*) five, less the absolute number one, by the unknown (*yāvat-tāvat*) three joined with the absolute two: Statement:⁴

$$\begin{array}{ll} ya & 5 \quad ru \ \dot{1} \\ ya & 3 \quad ru \ 2 \end{array} \quad \text{Product: } ya \ v \ 15 \quad ya \ 7 \quad ru \ \dot{2}.$$

"Example:⁵ 'So much as' three, 'black' five, 'blue' seven, all affirmative: how many do they make with negative two, three, and one of the same respectively, added to or subtracted from them? Statement:⁶

$$\begin{array}{lll} ya & 3 & ca \ 5 \quad ni \ 7 \\ ya & \dot{2} & ca \ \dot{3} \quad ni \ \dot{1} \end{array} \quad \begin{array}{l} \text{Answer: Sum } ya \ 1 \quad ca \ 2 \quad ni \ 6. \\ \text{Difference } ya \ 5 \quad ca \ 8 \quad ni \ 8. \end{array}$$

"Example:⁷ Say, friend, [find] the sum and difference of two irrational numbers eight and two: after full consideration, if thou be acquainted with the sixfold rule of surds. Statement:⁸ $c \ 2 \ c \ 8$.

¹ *Ibid.* ² In modern notation, $x+1$ and $2x-8$ have the sum $3x-7$.

³ Colebrooke, *op. cit.*, p. 141, 142.

⁴ In modern notation $(5x-1)(3x+2)=15x^2+7x-2$.

⁵ Colebrooke, *op. cit.*, p. 144.

⁶ In modern symbols, $3x+5y+7z$ and $-2x-3y-z$ have the sum $x+2y+6z$, and the difference $5x+8y+8z$.

⁷ Colebrooke, *op. cit.*, p. 146.

⁸ In modern symbols, the example is $\sqrt{8}+\sqrt{2}=\sqrt{18}$, $\sqrt{8}-\sqrt{2}=\sqrt{2}$. The same example is given earlier by Brahmagupta in his *Brahme-spūla-sidd'hānta*, chap. xviii, in Colebrooke, *op. cit.*, p. 341.

Answer: Addition being made, the sum is c 18. Subtraction taking place, the difference is c 2."

ARABIC: AL-KHOWÂRIZMÎ, NINTH CENTURY A.D.

115. In 772 Indian astronomy became known to Arabic scholars. As regards algebra, the early Arabs failed to adopt either the Diophantine or the Hindu notations. The famous *Algebra* of al-Khowârizmî of Bagdad was published in the original Arabic, together with an English translation, by Frederic Rosen,¹ in 1831. He used a manuscript preserved in the Bodleian Collection at Oxford. An examination of this text shows that the exposition was altogether rhetorical, i.e., devoid of all symbolism. "Numerals are in the text of the work always expressed by words: [Hindu-Arabic] figures are only used in some of the diagrams, and in a few marginal notes."² As a specimen of al-Khowârizmî's exposition we quote the following from his *Algebra*, as translated by Rosen:

"What must be the amount of a square, which, when twenty-one dirhems are added to it, becomes equal to the equivalent of ten roots of that square? Solution: Halve the number of the roots; the moiety is five. Multiply this by itself; the product is twenty-five. Subtract from this the twenty-one which are connected with the square; the remainder is four. Extract its root; it is two. Subtract this from the moiety of the roots, which is five; the remainder is three. This is the root of the square which you required, and the square is nine. Or you may add the root to the moiety of the roots; the sum is seven; this is the root of the square which you sought for, and the square itself is forty-nine."³

By way of explanation, Rosen indicates the steps in this solution, expressed in modern symbols, as follows: Example:

$$x^2 + 21 = 10x ; \quad x = \frac{1}{2} \pm \sqrt{\left[\left(\frac{1}{2}\right)^2 - 21\right]} = 5 \pm \sqrt{25 - 21} = 5 \pm \sqrt{4} = 5 \pm 2 .$$

ARABIC: AL-KARKHÎ, EARLY ELEVENTH CENTURY A.D.

116. It is worthy of note that while Arabic algebraists usually build up the higher powers of the unknown quantity on the multiplicative principle of the Hindus, there is at least one Arabic writer, al-Karkhî of Bagdad, who followed the Diophantine additive principle.⁴

¹ *The Algebra of Mohammed Ben Musa* (ed. and trans. Frederic Rosen; London, 1831). See also L. C. Karpinski, *Robert of Chester's Latin Translation of the Algebra of Al-Khowarizmi* (1915).

² Rosen, *op. cit.*, p. xv.

³ *Ibid.*, p. 11.

⁴ See Cantor, *op. cit.*, Vol. I (3d ed.), p. 767, 768; Heath, *op. cit.*, p. 41.

In al-Kharkī's work, the *Fakhrī*, the word *mal* means x^2 , *kaʿb* means x^3 ; the higher powers are *māl māl* for x^4 , *māl kaʿb* for x^5 (not for x^6), *kaʿb kaʿb* for x^6 (not for x^9), *māl māl kaʿb* for x^7 (not for x^{12}), and so on.

Cantor¹ points out that there are cases among Arabic writers where *māl* is made to stand for x , instead of x^2 , and that this ambiguity is reflected in the early Latin translations from the Arabic, where the word *census* sometimes means x , and not x^2 .²

BYZANTINE: MICHAEL PSELLUS, ELEVENTH CENTURY A.D.

117. Michael Psellus, a Byzantine writer of the eleventh century who among his contemporaries enjoyed the reputation of being the first of philosophers, wrote a letter³ about Diophantus, in which he gives the names of the successive powers of the unknown, used in Egypt, which are of historical interest in connection with the names used some centuries later by Nicolas Chuquet and Luca Pacioli. In Psellus the successive powers are designated as the first number, the second number (square), etc. This nomenclature appears to have been borrowed, through the medium of the commentary by Hypatia, from Anatolius, a contemporary of Diophantus.⁴ The association of the successive powers of the unknown with the series of natural numbers is perhaps a partial recognition of exponential values, for which there existed then, and for several centuries that followed Psellus, no adequate notation. The next power after the fourth, namely, x^5 , the Egyptians called "the first undescribed," because it is neither a square nor a cube; the sixth power they called the "cube-cube"; but the seventh was "the second undescribed," as being the product of the square and the "first undescribed." These expressions for x^5 and x^7 are closely related to Luca Pacioli's *primo relato* and *secondo relato*, found in his *Summa* of 1494.⁵ Was Pacioli directly or indirectly influenced by Michael Psellus?

ARABIC: IBN ALBANNA, THIRTEENTH CENTURY A.D.

118. While the early Arabic algebras of the Orient are characterized by almost complete absence of signs, certain later Arabic works on

¹ *Op. cit.*, p. 768. See also Karpinski, *op. cit.*, p. 107, n. 1.

² Such translations are printed by G. Libri, in his *Histoire des sciences mathématiques*, Vol. I (Paris, 1838), p. 276, 277, 305.

³ Reproduced by Paul Tannery, *op. cit.*, Vol. II (1895), p. 37-42.

⁴ See Heath, *op. cit.*, p. 2, 18.

⁵ See *ibid.*, p. 41; Cantor, *op. cit.*, Vol. II (2d ed.), p. 317.

algebra, produced in the Occident, particularly that of al-Qalasâdî of Granada, exhibit considerable symbolism. In fact, as early as the thirteenth century symbolism began to appear; for example, a notation for continued fractions in al-Ḥaṣṣâr (§ 391). Ibn Khaldûn¹ states that Ibn Albanna at the close of the thirteenth century wrote a book when under the influence of the works of two predecessors, Ibn Almunçim and Alahdab. "He [Ibn Albanna] gave a summary of the demonstrations of these two works and of other things as well, concerning the technical employment of symbols² in the proofs, which serve at the same time in the abstract reasoning and the representation to the eye, wherein lies the secret and essence of the explication of theorems of calculation with the aid of signs." This statement of Ibn Khaldûn, from which it would seem that symbols were used by Arabic mathematicians before the thirteenth century, finds apparent confirmation in the translation of an Arabic text into Latin, effected by Gerard of Cremona (1114-87). This translation contains symbols for x and x^2 which we shall notice more fully later. It is, of course, quite possible that these notations were introduced into the text by the translator and did not occur in the original Arabic. As regards Ibn Albanna, many of his writings have been lost and none of his extant works contain algebraic symbolism.

CHINESE: CHU SHIH-CHIEH

(1303 A.D.)

119. Chu Shih-Chieh bears the distinction of having been "instrumental in the advancement of the Chinese abacus algebra to the highest mark it has ever attained."³ The Chinese notation is interesting as being decidedly unique. Chu Shih-Chieh published in 1303 a treatise, entitled *Szu-yuen Yü-chien*, or "The Precious Mirror of the Four Elements," from which our examples are taken. An expression like $a+b+c+d$, and its square, $a^2+b^2+c^2+d^2+2ab+2ac+2ad+$

¹ Consult F. Woepeke, "Recherches sur l'histoire des sciences mathématiques chez les orientaux," *Journal asiatique* (5th ser.), Vol. IV (Paris, 1854), p. 369-72; Woepeke quotes the original Arabic and gives a translation in French. See also Cantor, *op. cit.*, Vol. I (3d ed.), p. 805.

² Or, perhaps, letters of the alphabet.

³ Yoshio Mikami, *The Development of Mathematics in China and Japan* (Leipzig, 1912), p. 89. All our information relating to Chinese algebra is drawn from this book, p. 89-98.

$2bc+2bd+2cd$, were represented as shown in the following two illustrations:

$$\begin{array}{ccccc}
 & & & & 1 \\
 & & & & 2 & 0 & 2 \\
 & & & & & 2 & \\
 1 & * & 1 & & 1 & 0 & * & 0 & 1 \\
 & & & & & 2 & \\
 & & & & 2 & 0 & 2 \\
 & & & & & 1 &
 \end{array}$$

Where we have used the asterisk in the middle, the original has the character *t'ai* ("great extreme"). We may interpret this symbolism by considering *a* located one space to the right of the asterisk (*), *b* above, *c* to the left, and *d* below. In the symbolism for the square of $a+b+c+d$, the 0's indicate that the terms *a*, *b*, *c*, *d* do not occur in the expression. The squares of these letters are designated by the 1's two spaces from *. The four 2's farthest from * stand for $2ab$, $2ac$, $2bc$, $2bd$, respectively, while the two 2's nearest to * stand for $2ac$ and $2bd$. One is impressed both by the beautiful symmetry and by the extreme limitations of this notation.

120. Previous to Chu Shih-Chieh's time algebraic equations of only one unknown number were considered; Chu extended the process to as many as four unknowns. These unknowns or elements were called the "elements of heaven, earth, man, and thing." Mikami states that, of these, the heaven element was arranged below the known quantity (which was called "the great extreme"), the earth element to the left, the man element to the right, and the thing element above. Letting * stand for the great extreme, and *x*, *y*, *z*, *u*, for heaven, earth, man, thing, respectively, the idea is made plain by the following representations:

$$\begin{array}{|c|} \hline * \\ \hline 1 \\ \hline \end{array} = x, \quad \begin{array}{|c|c|} \hline 1 & * \\ \hline \end{array} = y, \quad \begin{array}{|c|c|} \hline * & 1 \\ \hline \end{array} = z, \quad \begin{array}{|c|} \hline 1 \\ \hline * \\ \hline \end{array} = u.$$

Mikami gives additional illustrations:

$$\begin{array}{|c|c|} \hline 0_2 & * \\ \hline 0 & 0 \\ \hline \end{array} \quad \begin{array}{|c|c|c|} \hline * & 0 & 1 \\ \hline 0 & 1 & \\ \hline \end{array} \quad \begin{array}{|c|c|c|c|} \hline 0_{-2} & * & 0 & 1 \\ \hline & 0 & 1 & \\ \hline \end{array} \quad \begin{array}{|c|c|c|} \hline -2 & * & 1 \\ \hline & 1 & \\ \hline \end{array} .$$

$+2yz \qquad \qquad xz+z^2 \qquad \qquad -2yz+xz+z^2=0 \qquad \qquad -2y+x+z=0$

Using the Hindu-Arabic numerals in place of the Chinese calculating pieces or rods, Mikami represents three equations, used by Chu, in the following manner:

	4	*	4
-1	0	2	1
		-1	

a

1	0	*	0	-1
		0		
		1		

b

	-1	
2	*	0
	2	

c

In our notation, the four equations are, respectively,

- a) $2x - x^2 + 4y - xy^2 + 4z + xy = 0$,
 b) $x^2 + y^2 - z^2 = 0$,
 c) $2x + 2y - u = 0$.

No sign of equality is used here. All terms appear on one side of the equation. Notwithstanding the two-dimensional character of the notation, which permits symbols to be placed above and below the starting-point, as well as to left and right, it made insufficient provision for the representation of complicated expressions and for easy methods of computation. The scheme does not lend itself easily to varying algebraic forms. It is difficult to see how, in such a system, the science of algebra could experience a rapid and extended growth. The fact that Chinese algebra reached a standstill after the thirteenth century may be largely due to its inelastic and faulty notation.

BYZANTINE: MAXIMUS PLANODES, FOURTEENTH CENTURY A.D.

121. Maximus Planudes, a monk of the first half of the fourteenth century residing in Constantinople, brought out among his various compilations in Greek an arithmetic,¹ and also scholia to the first two books of Diophantus' *Arithmetica*.² These scholia are of interest to us, for, while Diophantus evidently wrote his equations in the running text and did not assign each equation a separate line, we find in Planudes the algebraic work broken up so that each step or each equation is assigned a separate line, in a manner closely resembling modern practice. To illustrate this, take the problem in Diophantus (i. 29),

¹ *Das Rechenbuch des Maximus Planudes* (Halle: herausgegeben von C. I. Gerhardt, 1865).

² First printed in Xylander's Latin translation of Diophantus' *Arithmetica* (Basel, 1575). These scholia in Diophantus are again reprinted in P. Tannery, *Diophanti Alexandrini opera omnia* (Lipsiae, 1895), Vol. II, p. 123-255; the example which we quote is from p. 201.

"to find two numbers such that their sum and the difference of their squares are given numbers." We give the exposition of Planudes and its translation.

Planudes		Translation	
$\bar{\kappa}$	$\bar{\pi}$	[Given the numbers], 20, 80	
$\epsilon\kappa\vartheta \cdot$	$s\bar{a}\mu^{\circ}\bar{\iota}$	$\mu^{\circ}\bar{\iota} \wedge s\bar{a}$	Putting for the numbers, $x+10$, $10-x$

ITALIAN: LEONARDO OF PISA

(1202 A.D.)

122. Leonardo of Pisa's mathematical writings are almost wholly rhetorical in mode of exposition. In his *Liber abbaci* (1202) he used the Hindu-Arabic numerals. To a modern reader it looks odd to see expressions like $\frac{1}{18} \frac{2}{11} \frac{3}{4} 42$, the fractions written before the integer in the case of a mixed number. Yet that mode of writing is his invariable practice. Similarly, the coefficient of x is written after the name for x , as, for example,¹ —"radices $\frac{1}{2}12$ " for $12\frac{1}{2}x$. A computation is indicated, or partly carried out, on the margin of the page, and is inclosed in a rectangle, or some irregular polygon whose angles are right angles. The reason for the inverted order of writing coefficients or of mixed numbers is due, doubtless, to the habit formed from the study of Arabic works; the Arabic script proceeds from right to left. Influenced again by Arabic authors, Leonardo uses frequent geometric figures, consisting of lines, triangles, and rectangles to illustrate his arithmetic or algebraic operations. He showed a partiality for unit fractions; he separated the numerator of a fraction from its denominator by a fractional line, but was probably not the first to do this (§ 235). The product of a and b is indicated by *factus ex.a.b*. It has been stated that he denoted multiplication by juxtaposition,² but G. Eneström shows by numerous quotations from the *Liber abbaci* that such is not the case.³ Cantor's quotation from the *Liber abbaci*,

¹ *Il liber abbaci di Leonardo Pisano* (ed. B. Boncompagni), Vol. I (Rome, 1867), p. 407.

² Cantor, *op. cit.*, Vol. II (2d ed.), p. 62.

³ *Bibliotheca mathematica* (3d ser.), Vol. XII (1910-11), p. 335, 336.

"sit numerus .a.e.c. quaedam coniunctio quae uocetur prima, numeri vero .d.b.f. sit coniunctio secunda,"¹ is interpreted by him as a product, the word *coniunctio* being taken to mean "product." On the other hand, Eneström conjectures that *numerus* should be *numeri*, and translates the passage as meaning, "Let the numbers *a*, *e*, *c* be the first, the numbers *d*, *b*, *f* the second combination." If Eneström's interpretation is correct, then *a.e.c* and *d.b.f* are not products. Leonardo used in his *Liber abbaci* the word *res* for *x*, as well as the word *radix*. Thus, he speaks, "et intellige pro re summam aliquam ignotam, quam inuenire uis."² The following passage from the *Liber abbaci* contains the words *numerus* (for a given number), *radix* for *x*, and *census* for *x*²: "Primus enim modus est, quando census et radices equantur numero. . . . Verbi gratia: duo census, et decem radices equantur denariis 30,"³ i.e., $2x^2 + 10x = 30$. The use of *res* for *x* is found also in a Latin translation of al-Khowârizmî's algebra,⁴ due perhaps to Gerard of Cremona, where we find, "res in rem fit census," i.e., $xx = x^2$. The word *radix* for *x* as well as *res*, and *substantia* for *x*², are found in Robert of Chester's Latin translation of al-Khowârizmî's algebra.⁵ Leonardo of Pisa calls *x*³ *cubus*, *x*⁴ *census census*, *x*⁶ *cubus cubus*, or else *census census census*; he says, ". . . est multiplicare per cubum cubi, sicut multiplicare per censum census census."⁶ He goes even farther and lets *x*⁸ be *census census census census*. Observe that this phraseology is based on the additive principle $x^2 \cdot x^2 \cdot x^2 \cdot x^2 = x^8$. Leonardo speaks also of *radix census census*.⁷

The first appearance of the abbreviation *R* or *℞* for *radix* is in his *Practica geometriae* (1220),⁸ where one finds the *℞* meaning "square root" in an expression "et minus *℞*. 78125 dragme, et diminuta radice 28125 dragme." A few years later, in Leonardo's *Flos*,⁹ one finds marginal notes which are abbreviations of passages in the text relating to square root, as follows:

FRENCH: NICOLE ORESME, FOURTEENTH CENTURY A.D.

123. Nicole Oresme (ca. 1323–82), a bishop in Normandy, prepared a manuscript entitled *Algorismus proportionum*, of which several copies are extant.¹ He was the first to conceive the notion of fractional powers which was afterward rediscovered by Stevin. More than this, he suggested a notation for fractional powers. He considers powers of ratios (called by him *proportiones*). Representing, as does Oresme himself, the ratio 2:1 by 2, Oresme expresses $2^{\frac{1}{2}}$ by the symbolism

$$\frac{1.p}{2.2}$$

and reads this *medietas* [*proportionis*] *duplae*; he expresses

$(2^{\frac{1}{2}})^{\frac{1}{2}}$ by the symbolism $\frac{1.p.1}{4.2.2}$ and reads it *quarta pars* [*proportionis*]

duplae sesquialterae. The fractional exponents $\frac{1}{2}$ and $\frac{1}{4}$ are placed to the left of the ratios affected.

H. Wieleitner adds that Oresme did not use these symbols in computation. Thus, Oresme expresses in words, “. . . proponatur proportio, que sit due tertie quadruple; et quia duo est numerator, ipsa erit vna tertia quadruple duplicate, sev sedecuple,”² i.e., $4^3 = (4^2)^{\frac{1}{2}} = 16^{\frac{1}{2}}$. Oresme writes³ also: “Sequitur quod .a. moueatur velocius .b. in proportione, que est medietas proportionis .50. ad .49.,” which means, “the velocity of *a*:velocity of *b* = $\sqrt{50}:\sqrt{49}$,” the word *medietas* meaning “square root.”⁴

The transcription of the passage shown in Figure 34 is as follows:

“Una media debet sic scribi $\frac{1}{2}$, una tertia sic $\frac{1}{3}$ et due tertie sic $\frac{2}{3}$; et sic de alijs. et numerus, qui supra uirgulam, dicitur

¹ Maximilian Curtze brought out an edition after the MS R. 4° 2 of the Gymnasiat-Bibliothek at Thorn, under the title *Der Algorithmus Proportionum des Nicolaus Oresme* (Berlin, 1868). Our photographic illustration is taken from that publication.

² Curtze, *op. cit.*, p. 15.

³ *Ibid.*, p. 24.

⁴ See Eneström, *op. cit.*, Vol. XII (1911–12), p. 181. For further details see also Curtze, *Zeitschrift für Mathematik und Physik*, Vol. XIII (Suppl. 1868), p. 65 ff.

numerator, iste uero, qui est sub uirgula, dicitur denominator. 2. Proportio dupla scribitur isto modo 2^{la} , et tripla isto modo 3^{la} ; et sic de alijs. Proportio sesquialtera sic scribitur $\frac{p \ 1}{1 \ 2}$, et sesquitertia

$\frac{p \ 1}{1 \ 3}$. Proportio superpartiens duas tertias scribitur sic $\frac{p \ 2}{1 \ 3}$.

Proportio dupla superpartiens duas quartas scribitur sic $\frac{p \ 2}{2 \ 4}$; et

sic de alijs. 3. Medietas duple scribitur sic $\frac{1 \ p}{2 \cdot 2}$, quarta pars

duple sesquialtere scribitur sic $\frac{1 \cdot p \ 1}{4 \cdot 2 \cdot 2}$; et sic de alijs."

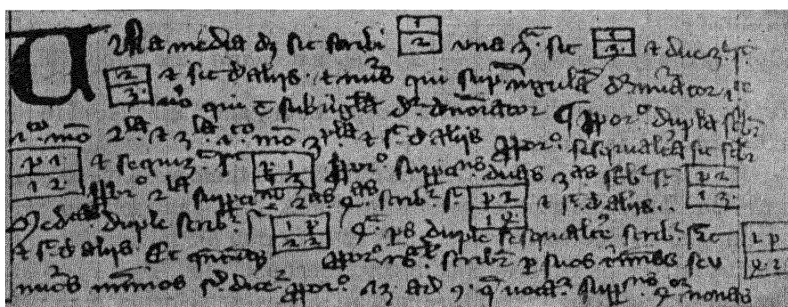

FIG. 34.—From the first page of Oresme's *Algorismus proportionum* (fourteenth century).

A free translation is as follows:

"Let a half be written $\frac{1}{2}$, a third $\frac{1}{3}$, and two-thirds $\frac{2}{3}$, and so on. And the number above the line is called the 'numerator,' the one below the line is called the 'denominator.' 2. A double ratio is written in this manner 2^{la} , a triple in this manner 3^{la} , and thus in other cases. The ratio one and one-half is written $\frac{p \ 1}{1 \ 2}$, and one and one-third is written $\frac{p \ 1}{1 \ 3}$. The ratio one and two-thirds is written

$\frac{p \ 2}{1 \ 3}$. A double ratio and two-fourths are written $\frac{p \ 2}{2 \ 4}$, and thus

in other cases. 3. The square root of two is written thus $\boxed{\frac{1. p}{2 \quad 2}}$, the fourth root of two and one-half is written thus $\boxed{\frac{1. p \quad 1}{4. \quad 2. \quad 2}}$, and thus in other cases."

ARABIC: AL-QALASÂDÎ, FIFTEENTH CENTURY A.D.

124. Al-Qalasâdî's *Raising of the Veil of the Science of Gubar* appeared too late to influence the progress of mathematics on the European Continent. Al-Qalasâdî used $\sqrt{}$, the initial letter in the Arabic word *jidr*, "square root"; the symbol was written above the number whose square root was required and was usually separated from it by a horizontal line. The same symbol, probably considered this time as the first letter in *jahala* ("unknown"), was used to represent the unknown term in a proportion, the terms being separated by the sign \therefore . But in the part of al-Qalasâdî's book dealing more particularly with algebra, the unknown quantity x is represented by the letter ش, x^2 by the letter ص, x^3 by the letter ك; these are written above their respective coefficients. Addition is indicated by juxtaposition. Subtraction is ـ ; the equality sign, = , is seen to resemble the Diophantine = , if we bear in mind that the Arabs wrote from right to left, so that the curved stroke faced in both cases the second member of the equation. We reproduce from Woepeke's article a few samples of al-Qalasâdî's notation. Observe the peculiar shapes of the Hindu-Arabic numerals (Fig. 35).

Woepeke¹ reproduces also symbols from an anonymous Arabic manuscript of unknown date which uses symbols for the powers of x and for the powers of the reciprocal of x , built up on the additive principle of Diophantus. The total absence of data relating to this manuscript diminishes its historic value.

GERMAN: REGIOMONTANUS

(ca. 1473)

125. Regiomontanus died, in the prime of life, in 1476. After having studied in Rome, he prepared an edition of Ptolemy² which was issued in 1543 as a posthumous publication. It is almost purely rhetorical, as appears from the following quotation on pages 21 and 22.

¹ *Op. cit.*, p. 375-80.

² *Ioannis de Monte Regio et Georgii Purbachii epitome, in Cl. Ptolemaei magnam compositionem* (Basel, 1543). The copy examined belongs to Mr. F. E. Brach.

By the aid of a quadrant is determined the angular elevation ACE , "que erit altitudo tropici hiemalis," and the angular elevation ACF , "que erit altitudo tropici aestivalis," it being required to find the arc EF between the two. "Arcus itaque EF , fiet distantia duorum tropi-

$$\begin{aligned} &\sqrt{60} \dots \frac{7}{60}; \quad \sqrt{5} \dots \frac{7}{5}; \quad \sqrt{12} \dots \frac{7}{12}; \\ &\sqrt{20 \frac{4}{7}} \dots \frac{7}{1} \frac{7}{20}; \quad \sqrt{6} \dots \frac{7}{6}; \quad \sqrt{\frac{3}{5}} \dots \frac{7}{5} \frac{7}{5}; \\ &3\sqrt{6} \dots \frac{7}{6}; \quad \sqrt{54} \dots \frac{7}{54}; \quad \frac{1}{2}\sqrt{48} \dots \frac{7}{8}; \quad \sqrt{12} \dots \frac{7}{12}. \end{aligned}$$

FORMULES D'ÉQUATIONS TRINÔMES.

$$\begin{aligned} x^2 + 10x = 56 &\dots \frac{7}{6} \frac{7}{10} \frac{7}{1}; \quad x^2 = 8x + 20 \dots \frac{7}{20} \frac{7}{1} \frac{7}{1}; \\ x^2 + 20 &= 12x \dots \frac{7}{12} \frac{7}{20} \frac{7}{1}; \quad x^2 + 16 = 8x \dots \frac{7}{8} \frac{7}{16} \frac{7}{1}^2; \\ 6x^2 + 12x &= 90 \dots \frac{7}{90} \frac{7}{12} \frac{7}{6}; \quad 4x^2 + 48 = 32x \dots \frac{7}{32} \frac{7}{48} \frac{7}{4}; \\ 3x^2 &= 12x + 63 \dots \frac{7}{63} \frac{7}{12} \frac{7}{3}; \quad \frac{1}{2}x^2 + x = 7\frac{1}{2} \dots \frac{7}{2} \frac{7}{1} \frac{7}{2}^3. \end{aligned}$$

PROPORTIONS.

$$\begin{aligned} 7 : 12 &= 84 : x \quad \dots \dots \frac{7}{84} \frac{7}{12} \frac{7}{x}; \\ 11 : 20 &= 66 : x \quad \dots \dots \frac{7}{66} \frac{7}{20} \frac{7}{x}. \end{aligned}$$

FIG. 35.—Al-Qalasâdî's algebraic symbols. (Compiled by F. Woepeke, *Journal asiatique* [Oct. and Nov., 1854], p. 363, 364, 366.)

corum quesita. Hâc Ptolemaeus reperit 47. graduum 42. minutorum 40. secundorum. Inuenit enim proportionem eius ad totum circulū sicut 11. ad 83, postea uerò minorem inuenerunt. Nos autem inuenimus arcum AF 65. graduum 6. minutorum, & arcum AE 18. graduum 10.

minutorum. Ideoq. nunc distantia tropicorum est 46. graduum 56. minutorum, ergo declinatio solis maxima nostro tempore est 23. graduum 28. minutorum."

126. We know, however, that in some of his letters and manuscripts symbols appear. They are found in letters and sheets containing computations, written by Regiomontanus to Giovanni Bianchini, Jacob von Speier, and Christian Roder, in the period 1463-71. These documents are kept in the Stadtbibliothek of the city of Nürnberg.¹ Regiomontanus and Bianchini designate angles thus: $\overset{gr}{\text{35}} \overset{m}{\text{17}}$; Regiomontanus writes also: $\overline{44}. 42'. 4''$ (see also § 127).

In one place² Regiomontanus solves the problem: Divide 100 by a certain number, then divide 100 by that number increased by 8; the sum of the quotients is 40. Find the first divisor. Regiomontanus writes the solution thus:

	In Modern Symbols	
$\frac{100}{1\mathcal{C}}$		$\frac{100}{x}$
$\frac{100}{1\mathcal{C} \text{ et } 8}$		$\frac{100}{x+8}$
100 \mathcal{C} et 800		100x+800
100 \mathcal{C}		100x
200 \mathcal{C} et 800 — 40		200x+800
1 \mathcal{C} et 8 \mathcal{C}		$\frac{200x+800}{x^2+8x} = 40$
40 \mathcal{C} et 320 \mathcal{C} — 200 \mathcal{C} et 800		40x ² +320x=200x+800.
40 \mathcal{C} et 120 \mathcal{C} — 800		40x ² +120x=800
1 \mathcal{C} et 3 \mathcal{C} — 20		$x^2 + 3x = 20$
$\frac{3}{2} \cdot \frac{9}{4}$ addo numerum 20 $\frac{3}{4}$ —8 $\frac{3}{4}$		$\frac{3}{2} \mid \frac{9}{4}$ add the no. 20 $\frac{3}{4}$ =8 $\frac{3}{4}$
Radix quadrata de 8 $\frac{3}{4}$ minus $\frac{3}{2}$ —1 \mathcal{C}		$\sqrt{8\frac{3}{4}} - \frac{3}{2} = x$
Primus ergo divisor fuit \mathcal{B} de 22 $\frac{1}{4}$		Hence the first divisor was
$\overline{19} 1\frac{1}{2}$."		$\sqrt{22\frac{1}{4}} - 1\frac{1}{2}$.

Note that "plus" is indicated here by *et*; "minus" by $\overline{19}$, which is probably a ligature or abbreviation of "minus." The unknown quantity is represented by \mathcal{C} and its square by \mathcal{C}^2 . Besides, he had a sign for equality, namely, a horizontal dash, such as was used later in Italy by Luca Pacioli, Ghaligai, and others. See also Fig. 36.

¹ Curtze, *Urkunden zur Geschichte der Mathematik im Mittelalter und der Renaissance* (Leipzig, 1902), p. 185-336 = *Abhandlungen zur Geschichte der Mathematik*, Vol. XII. See also L. C. Karpinski, *Robert of Chester's Translation of the Algebra of Al-Khowarizmi* (1915), p. 36, 37.

² Curtze, *op. cit.*, p. 278.

127. Figure 37¹ illustrates part of the first page of a calendar issued by Regiomontanus. It has the heading *Janer* ("January"). Farther to the right are the words *Sunne—Monde—Stainpock* ("Sun—Moon—Capricorn"). The first line is *1 A. Kl. New Jar* (i.e., "first day, A. calendar, New Year"). The second line is *2. b. 4. nō. der achtet S. Stephans*. The seven letters *A, b, c, d, e, F, g*, in the second column on the left, are the dominical letters of the calendars. Then come the days of the Roman calendar. After the column of saints' days comes a double column for the place of the sun. Then follow two double columns for the moon's longitude; one for the mean, the other for the

FIG. 36.—Computations of Regiomontanus, in letters of about 1460. (From manuscript, Nürnberg, fol. 23. (Taken from J. Tropicke, *Geschichte der Elementar-Mathematik* (2d ed.), Vol. II [1921], p. 14.)

true. The *S* signifies *signum* (i.e., 30°); the *G* signifies *gradus*, or "degree." The numerals, says De Morgan, are those facsimiles of the numerals used in manuscripts which are totally abandoned before the end of the fifteenth century, except perhaps in reprints. Note the shapes of the 5 and 7. This almanac of Regiomontanus and the *Computus* of Anianus are the earliest almanacs that appeared in print.

ITALIAN: THE EARLIEST PRINTED ARITHMETIC

(1478)

128. The earliest arithmetic was printed anonymously at Treviso, a town in Northeastern Italy. Figure 38 displays the method of solving proportions. The problem solved is as follows: A courier travels from Rome to Venice in 7 days; another courier starts at the same time and travels from Venice to Rome in 9 days. The distance between Rome and Venice is 250 miles. In how many days will the

by 112, according to the scratch method. Similarly is solved the proportion $9:250 = \frac{9}{112}:x$. Notice that the figure 1 is dotted in the same way as the Roman I is frequently dotted. Figure 39 represents other examples of multiplication.¹

FRENCH: NICOLAS CHUQUET

(1484)

129. Over a century after Oresme, another manuscript of even greater originality in matters of algebraic notation was prepared in France, namely, *Le triparty en la science des nombres* (1484), by Nicolas Chuquet, a physician in Lyons.² There are no indications that he had seen Oresme's manuscripts. Unlike Oresme, he does not use fractional exponents, but he has a notation involving integral, zero, and negative exponents. The only possible suggestion for such exponential notation known to us might have come to Chuquet from the Gobar numerals, the Fihrist, and from the scholia of Neophytos (§§ 87, 88) which are preserved in manuscript in the National Library at Paris. Whether such connection actually existed we are not able to state. In any case, Chuquet elaborates the exponential notation to a completeness apparently never before dreamed of. On this subject Chuquet was about one hundred and fifty years ahead of his time; had his work been printed at the time when it was written, it would, no doubt, have greatly accelerated the progress of algebra. As it was, his name was known to few mathematicians of his time.

Under the head of "Numeration," the *Triparty* gives the Hindu-Arabic numerals in the inverted order usual with the Arabs: ".0.9.8.7.6.5.4.3.2.1." and included within dots, as was customary in late manuscripts and in early printed books. Chuquet proves addition by "casting out the 9's," arranging the figures as follows:

$$\begin{array}{r}
 1\ 3 \\
 5\ 2 \\
 10\ 4 \\
 \hline
 16\ 9
 \end{array}
 \begin{array}{l}
 \diagup \\
 \diagdown \\
 \diagup \\
 \diagdown \\
 \hline
 \diagup
 \end{array}
 \begin{array}{l}
 .7. \\
 .7.
 \end{array}$$

¹ *Ibid.*, p. 550.

² *Op. cit.* (publié d'après le manuscrit fonds Français N. 1346 de la Bibliothèque nationale de Paris et précédé d'une notice, par M. Aristide Marre), *Bullettino di Bibliog. e di Storia delle scienze mat. et fisiche*, Vol. XIII (1880), p. 555-659, 693-814; Vol. XIV, p. 413-60.

The addition of $\frac{3}{4}$ and $\frac{4}{3}$ is explained in the text, and the following arrangement of the work is set down by itself:¹

$$\begin{array}{ccc} 3 & \searrow & 2 \\ 4 & \nearrow & 3 \\ 8. & & 9. \end{array}$$

130. In treating of roots he introduces the symbol R , the first letter in the French word *racine* and in the Latin *radix*. A number, say 12, he calls *racine premiere*, because 12, taken as a factor once, gives 12; 4 is a *racine seconde* of 16, because 4, taken twice as a factor, gives 16. He uses the notations $R^1.12$. equal .12., $R^2.16$. equal .4., $R^4.16$. equal .2., $R^5.32$. equal .2. To quote: "Il conuiendroit dire que racine premiere est entendue pour tous nombres simples Côme qui diroit la racine premiere de .12. que lon peult ainsi noter en mettant .1. dessus R . en ceste maniere $R^1.12$. cest .12. Et $R^1.9$. est .9. et ainsi de tous aultres nobres. Racine seconde est celle qui posee en deux places lune soubz laultre et puy multiplie lune par laultre pduyt le nombre duquel elle est racine seconde Comme 4. et .4. qui multipliez lung par laultre sont .16. ainsi la racine seconde de .16. si est .4. ... on le peult ainsi mettre $R^2.16$ Et $R^5.32$. si est .2. Racine sixe se doit ainsi mettre R^6 . et racine septiesme ainsi R^7 Aultres manieres de racines sont que les simples devant dictes que lon peult appeller racines composees Côme de 14. plus $R^2.180$. dont sa racine seconde si est .3. \bar{p} . $R^2.5$. [i.e., $\sqrt{14+\sqrt{180}}=3+\sqrt{5}$] ... cõe la racine seconde de .14. \bar{p} $R^2.180$. se peult ainsi mettre $R^2.14.\bar{p}.R^2.180$."²

Not only have we here a well-developed notation for roots of integers, but we have also the horizontal line, drawn underneath the binomial $14+\sqrt{180}$, to indicate aggregation, i.e., to show that the square root of the entire binomial is intended.

Chuquet took a position in advance of his time when he computed with zero as if it were an actual quantity. He obtains,³ according to his rule, $x=2\pm\sqrt{4-4}$ as the roots of $3x^2+12=12x$. He adds: "... reste .0. Donc $R^2.0$. adioustee ou soustraicte avec .2. ou de .2. monte .2. qui est le nøb^e que lon demande."

131. Chuquet uses \bar{p} and \bar{m} to designate the words *plus* and *moins*. These abbreviations we shall encounter among Italian writers. Proceeding to the development of his exponential theory and notation,

¹ Boncompagni, *Bullettino*, Vol. XIII, p. 636.

² *Ibid.*, p. 655.

³ *Ibid.*, p. 805; Eneström, *Bibliotheca mathematica*, Vol. VIII (1907-8), p. 203.

he states first that a number may be considered from different points of view.¹ One is to take it without any denomination (*sans aulcune denominacion*), or as having the denomination 0, and mark it, say, .12^o and .13^o. Next a number may be considered the primary number of a continuous quantity, called "linear number" (*nombre linear*), designated .12ⁱ .13ⁱ .20ⁱ, etc. Third, it may be a secondary or superficial number, such as 12². 13². 19², etc. Fourth, it may be a cubical number, such as .12³. 15³. 1³, etc. "On les peult aussi entendre estre nombres quartz ou quarrez de quarrez qui seront ainsi signez . 12⁴. 18⁴. 30⁴, etc." This nomenclature resembles that of the Byzantine monk Psellus of the eleventh century (§ 117).

Chuquet states that the ancients called his primary numbers "things" (*choses*) and marked them . ρ .; the secondary numbers they called "hundreds" and marked them . τ .; the cubical numbers they indicated by \square ; the fourth they called "hundreds of hundreds" (*champs de champ*), for which the character was $\tau\tau$. This ancient nomenclature and notation he finds insufficient. He introduces a symbolism "que lon peult noter en ceste maniere $R^2.12^i$. $R^2.12^2$. $R^2.12^3$. $R^2.12^4$. etc. $R^3.12^i$. $R^3.12^2$. $R^3.12^3$. $R^3.12^4$. etc. $R^4.13^5$. $R^6.12^6$. etc." Here " $R^4.13^5$," means $\sqrt[4]{13x^5}$. He proceeds further and points out "que lon peult ainsi noter .12ⁱ \tilde{m} ou moins 12,," thereby introducing the notion of an exponent "minus one." As an alternative notation for this last he gives ". $\tilde{m}.12^i$," which, however, is not used again in this sense, but is given another interpretation in what follows.

From what has been given thus far, the modern reader will probably be in doubt as to what the symbolism given above really means. Chuquet's reference to the ancient names for the unknown and the square of the unknown may have suggested the significance that he gave to his symbols. His 12² does not mean 12×12 , but our $12x^2$; the exponent is written without its base. Accordingly, his ".12ⁱ \tilde{m} ," means $12x^{-1}$. This appears the more clearly when he comes to "adiouster 8ⁱ avec $\tilde{m}.5^i$ monte tout .3ⁱ. Ou .10ⁱ avec $\tilde{m}.16^i$ môte tout $\tilde{m}.6^i$," i.e., $8x - 5x = 3x$, $10x - 16x = -6x$. Again, ".8² avec .12² montent .20²," means $8x^2 + 12x^2 = 20x^2$; subtracting " $\tilde{m}.16^i$ " from ".12²" leaves "12² \tilde{m} . \tilde{m} . 16^o qui valent autant cōme .12² \bar{p} . 16^o,"² The meaning of Chuquet's ".12^o" appears from his "Exemple. qui multiplie .12^o par .12^o montent .144. puis qui adioust .0. avec .0. monte 0. ainsi monte ceste multiplicacion .144^o,"³ i.e., $12x^0 \times 12x^0 =$

¹ Boncompagni, *op. cit.*, Vol. XIII, p. 737.

² *Ibid.*, p. 739.

³ *Ibid.*, p. 740.

$144x^0$. Evidently, $x^0=1$; he has the correct interpretation of the exponent zero. He multiplies $.12^2$ by $.10^2$ and obtains 120^2 ; also $.5^1$ times $.8^1$ yields $.40^2$; $.12^3$ times $.10^5$ gives $.120^8$; $.8^1$ times $.7^1 \cdot \tilde{m}$ gives $.56^0$ or $.56$; $.8^3$ times $.7^1 \cdot \tilde{m}$ gives $.56^2$. Evidently algebraic multiplication, involving the product of the coefficients and the sum of the exponents, is a familiar process with Chuquet. Nevertheless, he does not, in his notation, apply exponents to given numbers, i.e., with him "3²" never means 9, it always means $3x^2$. He indicates (p. 745) the division of $30-x$ by x^2+x in the following manner:

$$\frac{30. \tilde{m}. 1^1}{1^2 \bar{p}. 1^1}.$$

As a further illustration, we give $R^2 \underline{1. \frac{1}{2}} \cdot \bar{p} R^2 24. \bar{p} R^2 1. \frac{1}{2}$, multiplied by $R^2 1. \frac{1}{2} \bar{p} R^2 24. \tilde{m} R^2 1. \frac{1}{2}$, gives $R^2 24$. This is really more compact and easier to print than our $\sqrt{1\frac{1}{2}+ \sqrt{24}+ \sqrt{1\frac{1}{2}}} \text{ times } \sqrt{1\frac{1}{2}+ \sqrt{24}} - \sqrt{1\frac{1}{2}} \text{ equals } \sqrt{24}$.

FRENCH: ÉSTIENNE DE LA ROCHE
(1520)

132. Éstienne de la Roche, Villefranche, published *Larismethique*, at Lyon in 1520, which appeared again in a second edition at Lyon in 1538, under the revision of Gilles Huguetan. De la Roche mentions Chuquet in two passages, but really appropriates a great deal from his distinguished predecessor, without, however, fully entering into his spirit and adequately comprehending the work. It is to be regretted that Chuquet did not have in De la Roche an interpreter acting with sympathy and full understanding. De la Roche mentions the Italian Luca Pacioli.

De la Roche attracted little attention from writers antedating the nineteenth century; he is mentioned by the sixteenth-century French writers Buteo and Gosselin, and through Buteo by John Wallis. He employs the notation of Chuquet, intermixed in some cases, by other notations. He uses Chuquet's \bar{p} and \tilde{m} for *plus* and *moins*, also Chuquet's radical notation R^2, R^3, R^4, \dots , but gives an alternative notation: $R \square$ for R^3 , HR for R^4 , $HR \square$ for R^6 . His strange uses of the geometric square are shown further by his writing \square to indicate the cube of the unknown, an old procedure mentioned by Chuquet.

The following quotation is from the 1538 edition of De la Roche, where, as does Chuquet, he calls the unknown and its successive powers by the names of primary numbers, secondary numbers, etc.:

"... vng chascun nombre est considere comme quantité continue que aultrement on dit nombre linear qui peult estre appelle chose ou premier: et telz nombres seront notez apposition de une unite au dessus deulx en ceste maniere 12^1 ou 13^1 , etc., ou telz nombres seront signes dung tel caracte apres eux comme $12.\rho.$ ou $13.\rho.$... cubes que lon peut ainsi marquer $12.^3$ ou $13.^3$ et ainsi $12 \square$ ou $13 \square$."

The translation is as follows:

"And a number may be considered as a continuous quantity, in other words, a linear number, which may be designated a thing or as primary, and such numbers are marked by the apposition of unity above them in this manner 12^1 or 13^1 , etc., or such numbers are indicated also by a character after them, like $12.\rho.$ or $13.\rho.$... Cubes one

FIG. 40.—Part of fol. 60B of De la Roche's *Larismethique* of 1520

may mark $12.^3$ or $13.^3$ and also $12 \square$. or $13 \square$." (We have here $12^1 = 12x$, $12.^3 = 12x^3$, etc.)

A free translation of the text shown in Figure 40 is as follows:

"Next find a number such that, multiplied by its root, the product is 10. Solution: Let the number be x . This multiplied by \sqrt{x} gives $\sqrt{x^3} = 10$. Now, as one of the sides is a radical, multiply each side by itself. You obtain $x^3 = 100$. Solve. There results the cube root of 100, i.e., $\sqrt[3]{100}$ is the required number. Now, to prove this, multiply $\sqrt[3]{100}$ by $\sqrt[3]{100}$. But first express $\sqrt[3]{100}$ as $\sqrt[6]{1000000}$, by multiplying 100 by itself, and you have $\sqrt[6]{1000000}$. This multiplied by $\sqrt[6]{100}$ gives $\sqrt[6]{100000000}$, which is the square root of the cube root, or the cube root of the square root, or $\sqrt[6]{1000000}$. Extracting the square root gives $\sqrt[3]{1000}$ which is 10, or reducing by the extraction of the cube root gives the square root of 100, which is 10, as before."

¹ See an article by Terquem in the *Nouvelles annales de mathématiques* (Terquem et Gerono), Vol. VI (1847), p. 41, from which this quotation is taken. For extracts from the 1520 edition, see Boncompagni, *op. cit.*, Vol. XIV (1881), p. 423.

The end of the solution of the problem shown in Figure 41 is in modern symbols as follows:

$$\begin{array}{r}
 \text{first } \sqrt{34+7} . \\
 x \text{ --- } x+1 \qquad x+4 \\
 2\frac{1}{2}x \qquad 1\frac{1}{2}x+4\frac{1}{2} \\
 \hline
 2\frac{1}{2}x^2+2\frac{1}{2}x \text{ --- } 1\frac{1}{2}x^2+10\frac{1}{2}x+18 \\
 x^2 \text{ --- } 8x+18 \\
 \qquad 4 \quad 16 \\
 \qquad \hline
 16 \sqrt{34+4} \text{ second.}
 \end{array}$$

[i.e., $x = \sqrt{34+4}$]

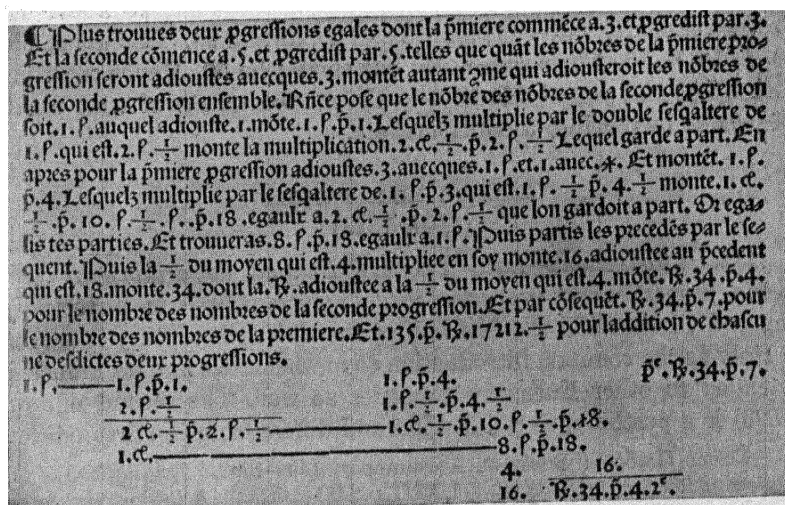

FIG. 41.—Part of fol. 66 of De la Roche's *Larismethique* of 1520

ITALIAN: PIETRO BORGHI (OR BORGHİ)
(1484, 1488)

133. Pietro Borgi's *Arithmetica* was first printed in Venice in 1484; we use the edition of 1488. The book contains no algebra. It displays the scratch method of division and the use of dashes in operating with fractions (§§ 223, 278). We find in this early printed *Arithmetica* the use of curved lines in the solution of problems in alligation. Such graphic aids became frequent in the solution of the indeterminate problems of alligation, as presented in arithmetics. Pietro Borgi, on the unnumbered folio 79B, solves the following problem: Five sorts of spirits, worth per *ster*, respectively, 44, 48, 52, 60, 66 *soldi*,

are to be mixed so as to obtain 50 *ster*, worth each 56 *soldi*. He solves this by taking the qualities of wine in pairs, always one quality dearer and the other cheaper than the mixture, as indicated by the curves in the example.

				16
				4
10	4	10	8	12
44	48	52	60	66
		56		

Then $56 - 44 = 12$; $66 - 56 = 10$; write 12 above 66 and 10 above 44. Proceed similarly with the pairs 48 and 60, 52 and 66. This done, add 10, 4, 10, 8, 16. Their sum is 48, but should be 50. Hence multiply each by $\frac{5}{4}$ and you obtain $10\frac{5}{2}$ as the number of *ster* of wine worth 44 *soldi* to be put into the mixture, etc.

ITALIAN: LUCA PACIOLI

(1494, 1523)

134. *Introduction*.—Luca Pacioli's *Summa de arithmetica geometria proportioni et proportionalita* (Venice, 1494)¹ is historically important because in the first half of the sixteenth century it served in Italy as the common introduction to mathematics and its influence extended to other European countries as well. The second edition (1523) is a posthumous publication and differs from the first edition

¹ Cosmo Gordon ("Books on Accountancy, 1494-1600," *Transactions of the Bibliographical Society* [London], Vol. XIII, p. 148) makes the following remarks on the edition of 1494: "The *Summa de arithmetica* occurs in two states. In the first the body of the text is printed in Proctor's type 8, a medium-sized gothic. On sig. a 1, on which the text begins, there is the broad wood-cut border and portrait-initial *L* already described. In the second state of the *Summa*, of which the copy in the British Museum is an example, not only do the wood-cut border and initial disappear from a 1, but sigs. a-c with the two outside leaves of sigs. d and e, and the outside leaf of sig. a, are printed in Proctor's type 10**, a type not observed by him in any other book from Paganino's press. There are no changes in the text of the reprinted pages, but that they are reprinted is clear from the fact that incorrect head-lines are usually corrected, and that the type of the remaining pages in copies which contain the reprints shows signs of longer use than in copies where the text type does not vary. It may be supposed that a certain number of the sheets of the signatures in question were accidentally destroyed, and that type 8 was already in use. The sheets had, therefore, to be supplied in the nearest available type." The copy of the 1494 edition in the Library of the University of California exhibits the type 10.

only in the spelling of some of the words. References to the number of the folio apply to both editions.

In the *Summa* the words "plus" and "minus," in Italian *più* and *meno*, are indicated by \tilde{p} and \tilde{m} . The unknown quantity was called "thing," in the Italian *cosa*, and from this word were derived in Germany and England the words *Coss* and "cossic art," which in the sixteenth and seventeenth centuries were synonymous with "algebra." As pointed out more fully later, *co.* (*cosa*) meant our x ; *ce.* (*censo*) meant our x^2 ; *cu.* (*cubo*) meant our x^3 . Pacioli used the letter R for *radix*. *Censo* is from the Latin *census* used by Leonardo of Pisa and Regiomontanus. Leonardo of Pisa used also the word *res* ("thing").

135. *Different uses of the symbol R.*—The most common use of R , the abbreviation for the word *radix* or *radici*, was to indicate roots. Pacioli employs for the same purpose the small letter λ , sometimes in the running text,¹ but more frequently when he is pressed for space in exhibiting algebraic processes on the margin.² He writes in Part I of his *Summa*:

- (Fol. 70B) $R.200.$ for $\sqrt{200}$
 (Fol. 119B) $R.cuba.de.64.$ for $\sqrt[3]{64}$
 (Fol. 182A)³ $R.relato.$ for fifth root
 (Fol. 182A) $R R R.cuba.$ for seventh root
 (Fol. 86A) $R.6.\tilde{m}.R.2.$ for $\sqrt{6-\sqrt{2}}$
 (Fol. 131A) $R R.120.$ for $\sqrt[4]{120}$
 (Fol. 182A) $R.cuba.de R.cuba.$ for sixth root
 (Fol. 182A) $R R.cuba.de R.cuba.$ for eighth root.

The use of the $Rv.$ for the designation of the roots of expressions containing two or more terms is shown in the following example:

- (Fol. 149A) $Rv. R.20\frac{1}{4}.\tilde{m}.\frac{1}{2}.$ for $\sqrt{\sqrt{20\frac{1}{4}}-\frac{1}{2}}.$

The following are probably errors in the use of $Rv.$:

- (Fol. 93A) $Rv. 50000.\tilde{m}.200.$ for $\sqrt{50,000-200},$
 (Fol. 93A) $R Rv. 50000.\tilde{m}.200.$ for $\sqrt{\sqrt{50,000-200}}.$

In combining symbols to express the higher roots, Pacioli uses the additive principle of Diophantus, while in expressing the higher powers

¹ Part I (1523), fol. 86 A.

² *Ibid.*, fol. 124 A.

³ On the early uses of *radix relata* and *primo relata* see Eneström, *Bibliotheca mathematica*, Vol. XI (1910-11), p. 353.

he uses the multiplication principle of the Hindus. Thus Pacioli indicates the seventh root by $R\ R\ R$. *cuba*. ($2+2+3$), but the eighth power by *ce.ce.ce*. ($2\times 2\times 2$). For the fifth, seventh, and eleventh powers, which are indicated by prime numbers, the multiplication principle became inapplicable. In that case he followed the notation of wide prevalence at that time and later: $p^{\circ}r^{\circ}$ (*primo relato*) for the fifth power, $2^{\circ}r^{\circ}$ (*secundo relato*) for the seventh power, $3^{\circ}r^{\circ}$ (*terzo relato*) for the eleventh power.¹ Whenever the additive principle was used in marking powers or roots, these special symbols became superfluous. Curiously, Pacioli applies the additive principle in his notation for roots, yet does not write $R.R\ cuba$ ($2+3$) for the fifth root, but R . *relata*. However, the seventh root he writes $R\ R\ R$. *cuba* ($2+2+3$) and not $R2^{\circ}r^{\circ}$.²

136. In other parts of Pacioli's *Summa* the sign R is assigned altogether different meanings. Apparently, his aim was to describe the various notations of his day, in order that readers might select the symbols which they happened to prefer. Referring to the prevailing diversity, he says, "tante terre: tante vsanze."³ Some historians have noted only part of Pacioli's uses of R , while others have given a fuller account but have fallen into the fatal error of interpreting certain powers as being roots. Thus far no one has explained all the uses of the sign R in Pacioli's *Summa*. It was Julius Rey Pastor and Gustav Eneström who briefly pointed out an inaccuracy in Moritz Cantor, when he states that Pacioli indicated by $R\ 30$ the thirtieth root, when Pacioli really designated by $R\ .30^a$ the twenty-ninth power. This point is correctly explained by J. Tropfke.⁴

We premise that Pacioli describes two notations for representing powers of an unknown, x^2 , x^3 , . . . , and three notations for x . The one most commonly used by him and by several later Italian writers of the sixteenth century employs for x , x^2 , x^3 , x^4 , x^5 , x^6 , x^7 , . . . , the abbreviations *co.* (*cosa*), *ce.* (*censo*), *cu.* (*cubo*), *ce.ce.* (*censo de censo*), $p^{\circ}r^{\circ}$ (*primo relato*), *ce.cu.* (*censo de cubo*), $2^{\circ}r^{\circ}$ (*secundo relato*), . . .⁵

Pacioli's second notation for powers involves the use of R , as already indicated. He gives: $R.p^a$ (*radix prima*) for x^0 , $R.2^a$ (*radix secunda*) for x , $R.3^a$ (*radix terza*) for x^2 , . . . , $R.30^a$ (*nono relato*) for x^{29} .⁶ When Eneström asserts that folio 67*B* deals, not with roots,

¹ Part I, fol. 67*B*.

² *Ibid.*, fol. 182*A*.

³ *Ibid.*, fol. 67*B*.

⁴ *Op. cit.* (2d ed.), Vol. II (1921), p. 109.

⁵ *Op. cit.*, Part I, fol. 67*B*.

⁶ *Ibid.*

but exclusively with the powers x^0 , x , x^2 , . . . , x^{29} , he is not quite accurate, for besides the foregoing symbols placed on the margin of the page, he gives on the margin also the following: "*Rx*. Radici; *R R*. Radici de Radici; *Rv*. Radici vniuersale. Ouer radici legata. O voi dire radici vnita; *R. cu*. Radici cuba; $\sqrt[3]{\beta}$ quantita." These expressions are used by Pacioli in dealing with roots as well as with powers, except that *Rv*. is employed with roots only; as we have seen, it signifies the root of a binomial or polynomial. In the foregoing two uses of *R*, how did Pacioli distinguish between roots and powers? The ordinal number, *prima*, *secunda*, *terza*, etc., placed after the *R*, always signifies a "power," or a *dignita*. If a root was intended, the number affected was written after the *R*; for example, *R*.200. for $\sqrt[2]{200}$. In folio 143AB Pacioli dwells more fully on the use of *R* in the designation of powers and explains the multiplication of such expressions as *R*. 5^a *via*. *R*. 11^a *fa* *R*. 15^a, i.e., $x^4 \times x^{10} = x^{14}$. In this notation one looks in vain for indications of the exponential concepts and recognition of the simple formula $a^m \cdot a^n = a^{m+n}$. Pacioli's results are in accordance with the formula $a^m \cdot a^n = a^{m+n-1}$. The ordinal numbers in *R* 11^a, etc., exceed by unity the power they represent. This clumsy designation made it seem necessary to Pacioli to prepare a table of products, occupying one and one-half pages, and containing over two hundred and sixty entries; the tables give the various combinations of factors whose products do not exceed x^{29} . While Eneström and Rey Pastor have pointed out that expressions like *R*.28^a mark powers and not roots, they have failed to observe that Pacioli makes no use whatever of this curious notation in the working of problems. Apparently his aim in inserting it was encyclopedial.

137. In working examples in the second part of the *Summa*, Pacioli exhibits a third use of the sign *R* not previously noted by historians. There *R* is used to indicate powers of numbers, but in a manner different from the notation just explained. We quote from the *Summa* a passage¹ in which *R* refers to powers as well as to roots. Which is meant appears from the mode of phrasing: "... *R*.108. e questo mēa con laxis ch' *R*.16. fa. *R*.1728 pigliā el $\frac{1}{3}$. cioe recca .3. a. *R*. 'a .9. parti .1728 in .9. neuien. 192. e. *R*. 192. . . ." ($\therefore \sqrt[3]{108}$ and multiplying this with the axis which is $\sqrt{16}$ gives $\sqrt{1,728}$. Take $\frac{1}{3}$, i.e., raising 3 to the second power gives 9; dividing 1,728 by 9 gives 192, and the $\sqrt{192}$) Here "recca. 3. a. *R*. fa. 9." identifies *R* with a power. In Part I, folio 186A, one reads, "quando fia recata prima. 1.

¹ *Ibid.*, Part II, fol. 72 B.

co. a. *R*. fa. 1. ce" ("raising the x to the second power gives x^2 "). Such phrases are frequent as, Part II, folio 72*B*, "reca. 2. a. *R*. cu. fa. 8" ("raise 2 to the third power; it gives 8"). Observe that *R. cu.* means the "third" power, while¹ *R. 3^a* and *R. terza.* refer to the "second" power. The expression of powers by the Diophantine additive plan (2+3) is exhibited in "reca. 3. a. *R R. cuba fa. 729*" ("raise 3 to the fifth power; it gives 729").²

A fourth use of *R* is to mark the unknown x . We have previously noted Pacioli's designation of x by *co.* (*cosa*) and by *R. 2^a*. In Part II, folio 15*B*, he gives another way: "la mita dun censo e .12. dramme: sonno equali a .5.*R*. E questo cōme a dire .10. radici sonno equali a vn censo e .24. dramme" ("Half of x^2 and the number 12 are equal to $5x$; and this amounts to saying $10x$ are equal to x^2 and the number 24").

In Part I, folio 60*B*, the sign *R* appears on the margin twice in a fifth rôle, namely, as the abbreviation for *rotto* ("fraction"), but this use is isolated. From what we have stated it is evident that Pacioli employed *R* in five different ways; the reader was obliged to watch his step, not to get into entanglements.

138. *Sign of equality*.—Another point not previously noted by historians is that Pacioli used the dash (—) as a symbol for equality. In Part I, folio 91*A*, he gives on the margin algebraic expressions relating to a problem that is fully explained in the body of the page. We copy the marginal notes and give the modern equivalents:

Summa (Part I, fol. 91A)		Modern Equivalents	
\bar{p}^2	1. co. \tilde{m} . 1. $\bar{q}\beta^2$	1st	$x - y$
3^2	1. co. \bar{p} . 1. $\bar{q}\beta^2$	3d	$x + y$
<hr/>		<hr/>	
	1. co. \tilde{m} . 1. ce. de. $\bar{q}\beta^2$ 36		$x^2 - y^2 = 36$
 <i>R</i> v. 1. ce. \tilde{m} 36 1. ce. $\bar{d}e$ $\bar{q}\beta^2$		$\sqrt{x^2 - 36} = y$,	
<i>Valor quantitatis.</i>		the value of y .	
p^2	1. co. \tilde{m} <i>R</i> v. 1. ce. \tilde{m} 36	1st	$x - \sqrt{x^2 - 36}$
2^2	6	2d	6
3^2	1. co. \bar{p} <i>R</i> v. 1. ce. \tilde{m} 36.	3d	$x + \sqrt{x^2 - 36}$
<hr/>		<hr/>	
	2. co. \bar{p} . 6.—216	$2x + 6$	$= 216$
	2. co. 210	$2x$	$= 210$
	<i>Valor rei.</i> 105	Value of x	105

¹ Part I, fol. 67*B*.² Part II, fol. 72*B*.

Notice that the *co.* in the third expression should be *ce.*, and that the .1. *ce. de $\overline{\beta}^a$* in the fourth expression should be .1. *co. de β^a* . Here, the short lines or dashes express equality. Against the validity of this interpretation it may be argued that Pacioli uses the dash for several different purposes. The long lines above are drawn to separate the sum or product from the parts which are added or multiplied. The short line or dash occurs merely as a separator in expressions like

$$\begin{array}{cc} \textit{Simplices} & \textit{Quadrata} \\ 3 & \text{-----} 9 \end{array}$$

in Part I, folio 39A. The dash is used in Part I, folio 54 B, to indicate multiplication, as in

$$\begin{array}{cc} 14 & 15 \\ 2 & 3 \\ \overline{5} & \overline{7} \end{array}$$

where the dash between 5 and 7 expresses 5×7 , one slanting line means 2×7 , the other slanting line 5×3 . In Part II, folio 37A, the dash represents some line in a geometrical figure; thus $d \text{---} 3 \text{---} k$ means that the line dk in a complicated figure is 3 units long. The fact that Pacioli uses the dash for several distinct purposes does not invalidate the statement that one of those purposes was to express equality. This interpretation establishes continuity of notation between writers preceding and following Pacioli. Regiomontanus,¹ in his correspondence with Giovanni Bianchini and others, sometimes used a dash for equality. After Pacioli, Francesco Ghaligai, in his *Pratica d'arithmetica*, used the dash for the same purpose. Professor E. Bortolotti informs me that a manuscript in the Library of the University of Bologna, probably written between 1550 and 1568, contains two parallel dashes (\equiv) as a symbol of equality. The use of two dashes was prompted, no doubt, by the desire to remove ambiguity arising from the different interpretations of the single dash.

Notice in Figure 42 the word *cosa* for the unknown number, and its abbreviation, *co.*; *censo* for the square of the unknown, and its contraction, *ce.*; *cubo* for the cube of the unknown; also . \tilde{p} . for "plus" and . \tilde{m} . for "minus." The explanation given here of the use of *cosa*, *censo*, *cubo*, is not without interest.

¹ See Maximilian Curtze, *Urkunden zur Geschichte der Mathematik im Mittelalter und der Renaissance* (Leipzig, 1902), p. 278.

The first part of the extract shown in Figure 43 gives $\sqrt[4]{\sqrt[4]{40+6} + \sqrt[4]{\sqrt[4]{40-6}}}$ and the squaring of it. The second part gives $\sqrt[4]{\sqrt[4]{20+2} + \sqrt[4]{\sqrt[4]{20-2}}}$ and the squaring of it; the simplified result is given as $\sqrt[4]{80+4}$, but it should be $\sqrt[4]{80+8}$. Remarkable in this second example is the omission of the v to express *universale*. From the computation as well as from the explanation of the text it appears that the first R was intended to express universal root, i.e., $\sqrt[4]{\sqrt[4]{20+2}}$ and not $\sqrt[4]{20+2}$.

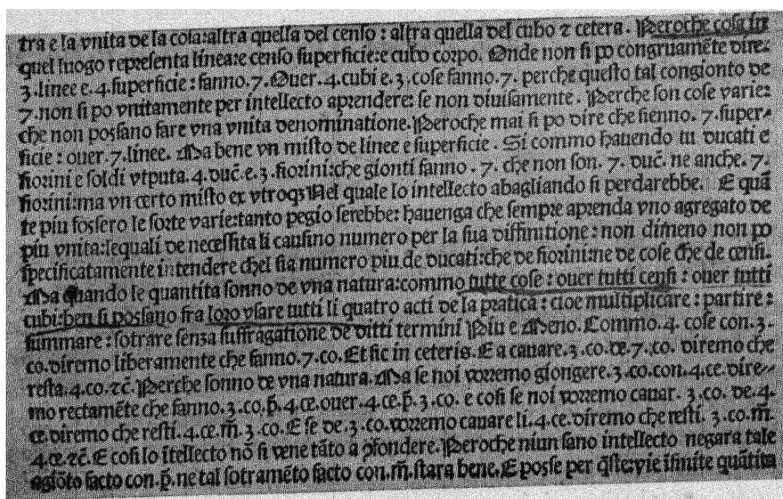

FIG. 42.—Part of a page in Luca Pacioli's *Summa*, Part I (1523), fol. 112A

ITALIAN: F. GHALIGAI

(1521, 1548, 1552)

139. Ghaligai's *Pratica d'arithmetica*¹ appeared in earlier editions, which we have not seen, in 1521 and 1548. The three editions do not differ from one another according to Riccardi's *Biblioteca matematica italiana* (I, 500–502). Ghaligai writes (fol. 71B): $x = \text{cosa} = c^{\circ}$, $x^2 = \text{censo} = \square$, $x^3 = \text{cubo} = \square\square$, $x^5 = \text{relato} = \square$, $x^7 = \text{pronico} = \square\square$, $x^{11} = \text{tronico} = \square\square\square$, $x^{13} = \text{dromico} = \square\square\square$. He uses the m° for “minus” and the \tilde{p} and e for “plus,” but frequently writes in full *piu* and *meno*.

¹ *Pratica d'arithmetica di Francesco Ghaligai Fiorentino* (Nuouamente Riuista, & con somma Diligenza Ristampata. In Firenze. M.D.LII).

Equality is expressed by dashes (— — —); a single dash (—) is used also to separate factors. The repetition of a symbol, simply to fill up an interval, is found much later also in connection with the sign of equality (=). Thus, John Wallis, in his *Mathesis universalis* ([Oxford, 1657], p. 104) writes: $1+2-3= = =0$.

Ghaligai uses his combinations of little squares to mark the orders of roots. Thus, folio 84B, $R \square di 3600 - che \grave{e} 60$, i.e., $\sqrt[4]{3,600} = 60$; folio 72B, $la R \square \square di 8 diciamo 2$, i.e., $\sqrt[4]{8} = 2$; folio 73B, $R \square \square di 7776$ for $\sqrt[5]{7,776}$; folio 73B, $R \square \square di \square di 262144$ for $\sqrt[6]{262,144}$.

ITALIAN: HIERONYMO CARDAN

(1539, 1545, 1570)

140. Cardan uses \tilde{p} and \tilde{m} for "plus" and "minus" and R for "root." In his *Practica arithmeticae generalis* (Milano, 1539) he uses Pacioli's symbols *nu.*, *co.*, *ce.*, *cu.*, and denotes the successive higher powers, *ce.ce.*, *Rel. p.*, *cu.ce.*, *Rel. 2.*, *ce.ce.ce.*, *cu.cu.*, *ce. Rel.*¹ However, in his *Ars magna* (1545) Cardan does not use *co.* for *x*, *ce.* for *x*², etc., but speaks of "rem ignotam, quam vocamus positionem,"² and writes $60 + 20x = 100$ thus: "60. \tilde{p} . 20. positionibus aequalia 100." Farther on³ he writes $x^2 + 2x = 48$ in the form "1. quad. \tilde{p} . 2. pos. aeq. 48," x^4 in the form⁴ "1. quadr. quad.," $x^5 + 6x^3 = 80$ in the form⁵ "r. $p^m \tilde{p}$. 6. cub. 80," $x^5 = 7x^2 + 4$ in the form⁶ "r^m p^m 7. quad. \tilde{p} . 4." Observe that in the last two equations there is a blank space where we write the sign of equality (=). These equations appear in the text in separate lines; in the explanatory text is given *aequale* or *aequatur*. For the representation of a second unknown he follows Pacioli in using the word *quantitas*, which he abbreviates to *quan.* or *qua.* Thus⁷ he writes $7x + 3y = 122$ in the form "7. pos. \tilde{p} . 3. qua. aequal. 122."

Attention should be called to the fact that in place of the \tilde{p} and \tilde{m} , given in Cardan's *Opera*, Volume IV (printed in 1663), one finds in Cardan's original publication of the *Ars magna* (1545) the signs *p*:

¹ *Hieronymi Cardani operum tomus quartus* (Lvgdvni, 1663), p. 14.

² *Ibid.*, p. 227.

³ *Ibid.*, p. 231.

⁴ *Ibid.*

⁵ *Ibid.*, p. 237.

⁶ *Ibid.*, p. 239.

⁷ *Ars magna* in *Operum tomus quartus*, p. 241, 242.

and m :. For example, in 1545 one finds $(5 + \sqrt{-15})(5 - \sqrt{-15}) = 25 - (-15) = 40$ printed in this form:

$$\begin{array}{r} \text{" } 5p: R m: 15 \\ 5m: R m: 15 \\ \hline 25m:m: 15 \text{ } \tilde{q}d \text{ est } 40 \text{ ,"} \end{array}$$

while in 1663 the same passage appears in the form:

$$\begin{array}{r} \text{" } 5. \bar{p}. R. \tilde{m}. 15. \\ 5. \tilde{m}. R. m. 15. \\ \hline 25. m. m. 15. quad. est 40. \text{"} \end{array}$$

141. Cardan uses R to mark square root. He employs² Pacioli's *radix universalis* to binomials and polynomials, thus " $R.V.7. \bar{p} R. 4.$ vel sic (R) $13.\bar{p} R. 9.$ " for $\sqrt{7+\sqrt{4}}$ or $\sqrt{13+\sqrt{9}}$; " $R.V.10.p.R.16.p.3.p R.64.$ " for $\sqrt{10+\sqrt{16+3+\sqrt{64}}}$. Cardan proceeds to new notations. He introduces the *radix ligata* to express the roots of each of the terms of a binomial; he writes: " $LR. 7. \bar{p}R. 10.$ "³ for $\sqrt{7+\sqrt{10}}$. This L would seem superfluous, but was introduced to distinguish between the foregoing form and the *radix distincta*, as in " $R.D. 9 p. R. 4.$," which signified 3 and 2 taken separately. Accordingly, " $R.D. 4. p. R. 9.$," multiplied into itself, gives $4+9$ or 13, while the " $R.L. 4. p. R. 9.$," multiplied into itself, gives $13+\sqrt{144}=25$. In later passages Cardan seldom uses the *radix ligata* and *radix distincta*.

In squaring binomials involving radicals, like " $R.V.L. R. 5. \bar{p}. R. 1. \tilde{m} R.V.L. R. 5. \tilde{m} R. 1.$," he sometimes writes the binomial a second time, beneath the first, with the capital letter X between the two binomials, to indicate cross-multiplication.⁴ Of interest is the following passage in the *Regula aliza* which Cardan brought out in 1570: " Rp : est p : $R m$: quadrata nulla est iuxta usum communem" ("The square root of a positive number is positive; the square root of a negative number is not proper, according to the common acceptance").⁵

However, in the *Ars magna*¹ Cardan solves the problem, to divide 10 into two parts, whose product is 40, and writes (as shown above):

$$\begin{array}{|l} \text{" } 5. \bar{p} \text{ R. } \bar{m}. 15. \\ \quad 5. \bar{m} \text{ R. } m.. 15. \\ \hline 25 m.m. 15. \text{ quad. est } 40. \text{ , ,} \end{array}$$

Exemplum. operationis. Probatio est, vt in exemp.o, cubus & quadrata 3. æquentur 21. æstimatione ex his regulis est, R. v. cubica $9\frac{1}{4} \bar{p}$. R. $89\frac{1}{4} \bar{p}$. FIG. 46.—Part of a page (255) from the *Ars magna* as reprinted in H. Cardan's *Operum tomus quartus* (Lvghvni, 1663). The *Ars magna* was first published in 1545.

¹ *Operum tomus quartus*, p. 287.

In one place Cardan not only designates known numbers by letters, but actually operates with them. He lets a and b stand for any given numbers and then remarks that $R \frac{a}{b}$ is the same as $\frac{Ra}{Rb}$, i.e., $\sqrt[3]{\frac{a}{b}}$ is the same as $\frac{\sqrt[3]{a}}{\sqrt[3]{b}}$.¹

Figure 46 deals with the cubic $x^3 + 3x^2 = 21$. As a check, the value of x , expressed in radicals, is substituted in the given equation. There are two misprints. The $226\frac{1}{2}$ should be $256\frac{1}{2}$. Second, the two lines which we have marked with a stroke on the left should be omitted, except the \tilde{m} at the end. The process of substitution is unnecessarily complicated. For compactness of notation, Cardan's symbols rather surpass the modern symbols, as will be seen by comparing his passage with the following translation:

"The proof is as in the example $x^3 + 3x^2 = 21$. According to these rules, the result is $\sqrt[3]{9\frac{1}{2} + \sqrt{89\frac{1}{4}}} + \sqrt[3]{9\frac{1}{2} - \sqrt{89\frac{1}{4}}} - 1$. The cube [i.e., x^3] is made up of seven parts:

$$\begin{aligned} &12 - \sqrt[3]{4,846\frac{1}{2} + \sqrt{23,487,833\frac{1}{4}}} - \sqrt[3]{4,846\frac{1}{2} - \sqrt{23,487,833\frac{1}{4}}} \\ &+ \sqrt[3]{46,041\frac{3}{4} + \sqrt{2,119,776,950\frac{3}{8}}} - \sqrt[3]{2,096,286,117\frac{9}{16}} \\ &+ \sqrt[3]{46,041\frac{3}{4} + \sqrt{2,096,354,180\frac{3}{8}}} - \sqrt[3]{2,119,776,950\frac{3}{8}} \\ &+ \sqrt[3]{256\frac{1}{2} + \sqrt{65,063\frac{1}{4}}} + \sqrt[3]{256\frac{1}{2} - \sqrt{65,063\frac{1}{4}}} . \end{aligned}$$

"The three squares [i.e., $3x^2$] are composed of seven parts in this manner:

$$\begin{aligned} &9 + \sqrt[3]{4,846\frac{1}{2} + \sqrt{23,487,833\frac{1}{4}}} \\ &+ \sqrt[3]{4,846\frac{1}{2} - \sqrt{23,487,833\frac{1}{4}}} \\ &- \sqrt[3]{256\frac{1}{2} + \sqrt{65,063\frac{1}{4}}} \\ &- \sqrt[3]{256\frac{1}{2} - \sqrt{65,063\frac{1}{4}}} \\ &- \sqrt[3]{256\frac{1}{2} + \sqrt{65,063\frac{1}{4}}} \\ &- \sqrt[3]{256\frac{1}{2} - \sqrt{65,063\frac{1}{4}}} . \end{aligned}$$

Now, adding the three squares with the six parts in the cube, which are equal to the general cube root, there results 21, for the required aggregate."

¹ *De regula aliza* (1570), p. 111. Quoted by Eneström, *op. cit.*, Vol. VII (1906-7), p. 387.

In translation, Figure 47 is as follows:

"The *Quaestio VIII.*

"Divide 6 into three parts, in continued proportion, of which the sum of the squares of the first and second is 4. We let the first be the

1. position [i.e., x]; its square is 1. square [i.e., x^2]. Hence 4 minus this is the square of the second quantity, i.e., 4—1. square [i.e., $4-x^2$]. Subtract from 6 the square root of this and also 1. position, and you will have the third quantity [i.e., $6-x-\sqrt{4-x^2}$], as you see, because the first multiplied by the third . . . :

$x \mid \sqrt{4-x^2} \mid 6-x-\sqrt{4-x^2} \mid$ $6x-x^2-\sqrt{4x^2-x^4}$
$4. \mid 6x-\sqrt{4x^2-x^4}$ $6x-4=\sqrt{4x^2-x^4}$ $36x^2+16-48x=4x^2-x^4$
$32x^2+16+x^4=48x$
$1x^4+32x^2+256=48x+240$

ITALIAN: NICOLÒ TARTAGLIA
(1537, 1543, 1546, 1556-60)

142. Nicolo Tartaglia's first publication, of 1537, contains little algebraic symbolism. He writes: "Radice .200. censi piu .10. cose" for $\sqrt{200x^2+10x}$, and "trouamo la cosa ualer Radice .200. men. 10." for "We find $x=\sqrt{200-10}$."¹ In his edition of Euclid's *Elements*² he writes "R R R R" for the sixteenth root. In his *Quesiti*³ of 1546 one reads, "Sia .1. cubo de censo piu .48. equal à 14. cubi" for "Let $x^6+48=14x^3$," and "la R. cuba de .8. ualera la cosa, cioe. 2." for "The $\sqrt[6]{8}$ equals x , which is 2."

More symbolism appeared ten years later. Then he used the \tilde{p} and \tilde{m} of Pacioli to express "plus" and "minus," also the *co.*, *ce.*, *cu.*, etc., for the powers of numbers. Sometimes his abbreviations are less intense than those of Pacioli, as when he writes⁴ *men* instead of \tilde{m} , or⁵ *cen* instead of *ce*. Tartaglia uses *R* for *radix* or "root." Thus "la R R di $\frac{1}{16}$ è $\frac{1}{2}$,"⁶ "la R cu. di $\frac{1}{8}$ è $\frac{1}{2}$,"⁷ "la R rel. di $\frac{1}{32}$ è $\frac{1}{2}$,"⁸ "la R cen. cu. di $\frac{1}{64}$ è $\frac{1}{2}$,"⁹ "la R cu. cu. di $\frac{1}{512}$ è $\frac{1}{2}$,"¹⁰ "la R terza rel. di $\frac{1}{2048}$ è $\frac{1}{2}$."¹¹

143. Tartaglia writes proportion by separating the three terms which he writes down by two slanting lines. Thus,¹² he writes "9//5//100," which means in modern notation $9:5=100:x$. For his occasional use of parentheses, see § 351.

FIG. 50.—From Bombelli's *L'algebra* (1572)

In Figure 50 the equations are:

$$\begin{aligned}
 4 + \sqrt{24 - 20x} &= 2x, \\
 \sqrt{24 - 20x} &= 2x - 4, \\
 24 - 20x &= 4x^2 - 16x + 16, \\
 24 + 16x &= 4x^2 + 20x + 16, \\
 24 &= 4x^2 + 4x + 16, \\
 8 &= 4x^2 + 4x, \\
 2 &= x^2 + x, \\
 2\frac{1}{2} &= x^2 + x + \frac{1}{4}, \\
 1\frac{1}{2} &= x + \frac{1}{2}, \\
 1 &= x.
 \end{aligned}$$

Bombelli expressed square root by *R. q.*, cube root by *R. c.*, fourth root by *R. R. q.*, fifth root (*Radice prima incomposta, ouer relata*) by *R. p. r.*, sixth root by *R. q. c.*, seventh root by *R. s. r.*, the square root of a polynomial (*Radice quadrata legata*) by *R. q. L. J.*; the cube root of a polynomial (*Radice cubica legata*) by *R. c. L. J.* Some of these symbols are shown in Figure 51. He finds the sum of $\sqrt[3]{72} - \sqrt{1,088}$ and $\sqrt[3]{4,352} + 16$ to be $\sqrt[3]{232} + \sqrt{53,312}$.

The first part of the sentence preceding page 161 of Bombelli's *Algebra*, as shown in Figure 51, is "Sommisi *R. c. L. R. q.* 4352 .p. 16. I con *R. c. L. 72. m. R. q.* 1088. I."

145. Bombelli's *Algebra* existed in manuscript about twenty years before it was published. The part of a page reproduced in Figure 52 is of interest as showing that the mode of expressing aggregation of terms is different from the mode in the printed texts. We have here the expression of the radicals representing x for the cubic $x^3 = 32x + 24$. Note the use of horizontal lines with cross-bars at the ends; the lines are placed below the terms to be united, as was the case in Chuquet. Observe also that here a negative number is not allowed to stand alone: -1069 is written $0 - 1069$. The cube root is designated by R^3 , as in Chuquet.

A manuscript, kept in the Library of the University of Bologna, contains data regarding the sign of equality ($=$). These data have been communicated to me by Professor E. Bortolotti and tend to show that ($=$) as a sign of equality was developed at Bologna independently of Robert Recorde and perhaps earlier.

The problem treated in Figure 53 is to divide 900 into two parts, one of which is the cube root of the other. The smaller part is desig-

FIG. 51.—Bombelli's *Algebra*, p. 161 of the 1579 impression, exhibiting the calculus of radicals. In the third line of the computation, instead of 18,415,616 there should be 27,852,800. Notice the broken fractional lines, indicating difficulty in printing fractions with large numerators and denominators.

nated by a symbol consisting of c and a flourish (probably intended for co). Then follows the equation $900 \tilde{m} 1co^{\textcircled{1}} = 1cu^{\textcircled{3}}$. (our $900 - x = x^3$). One sees here a mixture of two notations for x and x^3 : the notation co and cu made familiar by Luca Pacioli, and Bombelli's exponential notation, with the 1 and 3, placed above the line, each exponent resting in a cup. It is possible that the part of the algebra here photographed may go back as far as about 1550. The cross-writing in the photograph begins: "in libro vecchio a carte 82: quella di far di 10 due parti: dice messer Nicolo che l'ona e $R \ 43 \ p \ 5 \ \tilde{m} \ R18$: et l'altra il resto sino a 10, cioe $5 \ \tilde{m} \ R \ 43 \ \tilde{p} \ . \ R \ 18$." This Nicolo is supposed to be Nicolo Tartaglia who died in 1557. The phrasing "Messer Nicolo" implies, so Bortolotti argues, that Nicolo was a living contemporary. If these contentions are valid, then the manuscript in question was written in 1557 or earlier.¹

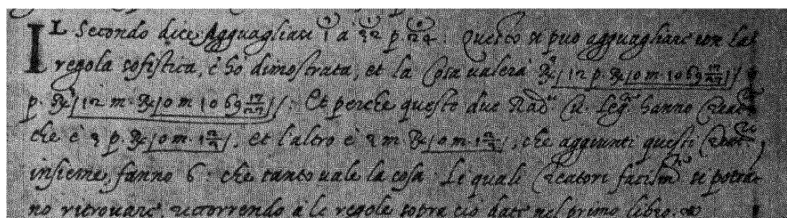

FIG. 52.—From the manuscript of the *Algebra* of Bombelli in the Comunale Library of Bologna. (Courtesy of Professor E. Bortolotti, of Bologna.)

The novel notations of Bombelli and of Ghaligai before him did not find imitators in Italy. Thus, in 1581 there appeared at Brescia the arithmetic and mensuration of Antonio Maria Visconti,² which follows the common notation of Pacioli, Cardan, and Tartaglia in designating powers of the unknown.

GERMAN: IOHANN WIDMAN
(1489, 1526)

146. Widman's *Behennde vnnd hübsche Rechnüg auff allen Kauffmanschaften* is the earliest printed arithmetic which contains the signs plus (+) and minus (−) (see §§ 201, 202).

¹ Since the foregoing was written, E. Bortolotti has published an article, on mathematics at Bologna in the sixteenth century, in the *Periodico di Matematiche* (4th ser., Vol. V, 1925), p. 147–84, which contains much detailed information, and fifteen facsimile reproductions of manuscripts exhibiting the notations then in use at Bologna, particularly the use of a dash (—) and the sign (=) to express equality.

² *Antonii Mariae Vicecomitis Civis Placentini practica numerorum & mensurarum* (Brixiae, 1581).

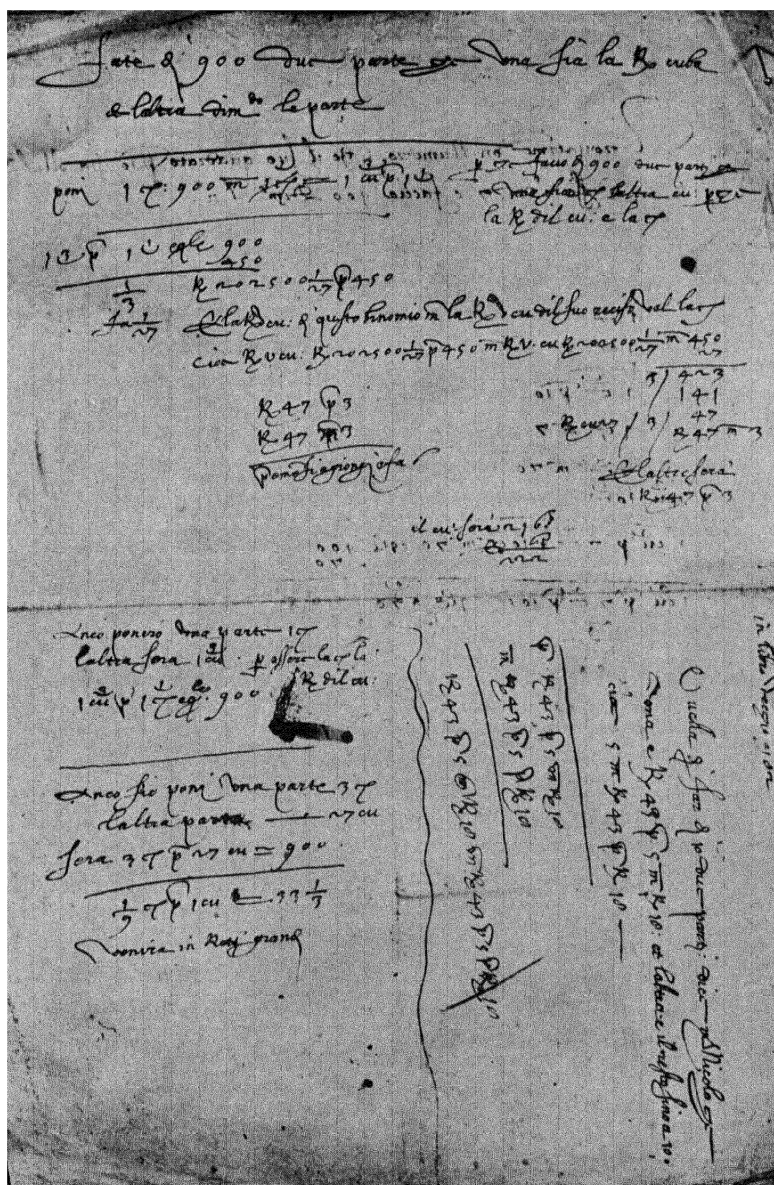

FIG. 53.—From a pamphlet (marked No. 595N, in the Library of the University of Bologna) containing studies and notes which Professor Bortolotti considers taken from the lessons of Pompeo Bolognetti ([Bologna?]-1568).

FIG. 57.—From the arithmetic of Grammateus (1518)

or *quart.* (*quarta*), *5a.* or *quit.* (*quinta*), *6a.* or *sex.* (*sexta*); *N.* stands for absolute number.

Fig. 56 shows addition of binomials. Figure 57 amounts to the solution of a quadratic equation. In translation: "The sixth rule: When in a proportioned number [i.e., in 1, x , x^2] three quantities are taken so that the first two added together are equal to the third [i.e.,

$d+ex=fx^2$], then the first shall be divided by [the coefficient of] the third and the quotient designated a . In the same way, divide the [coefficient of] the second by the [coefficient of] the third and the quotient designated b . Then multiply the half of b into itself and to the square add a ; find the square root of the sum and add that to half of b . Thus is found the N . of 1 *pri*. [i.e., the value of x]. Place the number successively in the seven-fold proportion

N :	x	x^2	x^3	x^4	x^5
1.	7	49	343.	2,401.	16,807.

Now I equate $12x+24$ with $2\frac{1}{4}\frac{9}{9}x^2$. Proceed thus: Divide 24 by $2\frac{1}{4}\frac{9}{9}x^2$; there is obtained $10\frac{8}{9}a$. Divide also $12x$ by $2\frac{1}{4}\frac{9}{9}x^2$; thus arises $5\frac{4}{9}b$. Multiplying the half of b by itself gives $2\frac{3}{4}\frac{9}{4}^1$, to which adding a , i.e., $10\frac{8}{9}$, will yield $5\frac{9}{3}\frac{2}{4}^2$, the square root of which is $7\frac{7}{8}$; add this to half of the part b or $4\frac{9}{8}$, and there results the number 7 as the number 1 *pri*. [i.e., x]."

The following example is quoted from Grammateus by Treutlein:!

" 6 <i>pri</i> . + 8 <i>N</i> .	Modern Symbols
Durch	$6x + 8$
5 <i>pri</i> . - 7 <i>N</i> .	$5x - 7$
<hr/>	<hr/>
30 <i>se</i> . + 40 <i>pri</i> .	$30x^2 + 40x$
- 42 <i>pri</i> . - 56 <i>N</i> .	$- 42x - 56$
<hr/>	<hr/>
30 <i>se</i> . - 2 <i>pri</i> . - 56 <i>N</i> . "	$30x^2 - 2x - 56$.

In the notation of Grammateus, 9 *ter*. + 30 *se*. - 6 *pri*. + 48*N*. stands for $9x^3 + 30x^2 - 6x + 48$.²

We see in Grammateus an attempt to discard the old cossic symbols for the powers of the unknown quantity and to substitute in their place a more suitable symbolism. The words *prima*, *seconda*, etc., remind one of the nomenclature in Chuquet. His notation was adopted by Gielis van der Hoecke.

GERMAN: CHRISTOFF RUDOLFF
(1525)

148. Rudolff's *Behend vnnd Hubsch Rechnung durch die kunstreichen regeln Algebre so gemeincklich die Coss geneñt werden* (Strass-

¹ P. Treutlein, *Abhandlungen zur Geschichte der Mathematik*, Vol. II (Leipzig, 1879), p. 39.

FIG. 58.—From Rudolff's *Coss* (1525)

side or root of a square. *Zensus*, the third in order, is always a square; it arises from the multiplication of the *radix* into itself. Thus, when *radix* means 2, then 4 is the *zensus*." Adam Riese assures us that these symbols were in general use ("zeichen ader benennung Di in gemeinen brauch teglich gehandelt werdenn").¹ They were adopted by Adam

¹ Riese's *Coss* was found, in manuscript, in the year 1855, in the Kirchen- und Schulbibliothek of Marienberg, Saxony; it was printed in 1892 in the following publication: *Adam Riese, sein Leben, seine Rechenbücher und seine Art zu rechnen. Die Coss von Adam Riese*, by Realgymnasialrektor Bruno Berlet, in Annaberg i. E., 1892.

Riese, Apian, Menher, and others. The addition of radicals is shown in Figure 59. Cube root is introduced in Rudolff's *Coss* of 1525 as follows: "Würt radix cubica in diesem algorithmo bedeut durch solchen character $\sqrt[3]{}$, als $\sqrt[3]{8}$ is zu versteen radix cubica aufs 8." ("In this algorithm the cubic root is expressed by this character $\sqrt[3]{}$, as $\sqrt[3]{8}$ is to be understood to mean the cubic root of 8.") The fourth root Rudolff indicated by $\sqrt[4]{}$; the reader naturally wonders why two strokes should signify fourth root when three strokes indicate cube root. It is not at once evident that the sign for the fourth

dan $\sqrt[4]{4}$ ist 2. $\sqrt[4]{9}$ ist 3. prungen in einer summa 5

FIG. 59.—From Rudolff's *Coss* (1525)

root represented two successive square-root signs, thus, $\sqrt{\sqrt{}}$. This crudeness in notation was removed by Michael Stifel, as we shall see later.

The following example illustrates Rudolff's subtraction of fractions:¹

$$\text{" } \frac{1 \mathcal{R} - 2}{12} \text{ von } \frac{12}{1 \mathcal{R} + 2} \text{ Rest } \frac{148 - 13}{12 \mathcal{R} + 24} \text{ "}$$

On page 141 of his *Coss*, Rudolff indicates aggregation by a dot;² i.e., the dot in " $\sqrt{\cdot 12 + \sqrt{140}}$ " indicates that the expression is $\sqrt{12 + \sqrt{140}}$, and not $\sqrt{12} + \sqrt{140}$. In Stifel sometimes a second dot appears at the end of the expression (§ 348). Similar use of the dot we shall find in Ludolph van Ceulen, P. A. Cataldi, and, in form of the colon (:), in William Oughtred.

When dealing with two unknown quantities, Rudolff represented

¹ Treutlein, "Die deutsche Coss," *op. cit.*, Vol. II, p. 40.

² G. Wertheim, *Abhandlungen zur Geschichte der Mathematik*, Vol. VIII (Leipzig, 1898), p. 153.

the second one by the small letter q , an abbreviation for *quantita*, which Pacioli had used for the second unknown.¹

Interesting at this early period is the following use of the letters a , c , and d to represent ordinary numbers (folio Gij^a): "Nim $\frac{1}{2}$ solchs collect | setz es auff ein ort | dz werd von lere wegen c genennt. Darnach subtrahier das c vom a | das übrig werd gesprochen d . Nun sag ich dz $\sqrt{c} + \sqrt{d}$ ist quadrata radix des ersten binomij." ("Take $\frac{1}{2}$ this sum, assume for it a position, which, being empty, is called c . Then subtract c from a , what remains call d . Now I say that $\sqrt{c} + \sqrt{d}$ is the square root of the first binomial.")²

149. Rudolff was convinced that development of a science is dependent upon its symbols. In the Preface to the second part of Rudolff's *Coss* he states: "Das bezeugen alte bücher nit vor wenig jaren von der coss geschriben, in welchen die quantitern, als dragma, res, substantia etc. nit durch character, sunder durch gantz geschribne wort dargegeben sein, vnd sunderlich in practicirung eines yeden exempels die frag gesetzt, ein ding, mit solchen worten, ponatur vna res." In translation: "This is evident from old books on algebra, written many years ago, in which quantities are represented, not by characters, but by words written out in full, 'drachm,' 'thing,' 'substance,' etc., and in the solution of each special example the statement was put, 'one thing,' in such words as *ponatur, una res*, etc."³

In another place Rudolff says: "Lernt die zalen der coss aussprechen vnnnd durch ire charakter erkennen vnd schreiben."⁴ ("Learn to pronounce the numbers of algebra and to recognize and write them by their characters.")

DUTCH: GIELIS VAN DER HOECKE

(1537)

150. An early Dutch algebra was published by Gielis van der Hoecke which appeared under the title, *In arithmetica een sonderlinge excellēt boeck* (Antwerp [1537]).⁵ We see in this book the early appear-

¹ Chr. Rudolff, *Behend vnnnd Hubsch Rechnung* (Strassburg, 1525), fol. R1^a. Quoted by Eneström, *Bibliotheca mathematica*, Vol. XI (1910-11), p. 357.

² Quoted from Rudolff by Eneström, *ibid.*, Vol. X (1909-10), p. 61.

³ Quoted by Gerhardt, *op. cit.* (1870), p. 153. This quotation is taken from the second part of Gerhardt's article; the first part appeared in the same publication, for the year 1867, p. 38-54.

⁴ *Op. cit.*, Buch I, Kap. 5, Bl. Dijr^o; quoted by Tropfke, *op. cit.* (2. ed.), Vol. II, p. 7.

⁵ On the date of publication, see Eneström, *op. cit.*, Vol. VII (1906-7), p. 211; Vol. X (1909-10), p. 87.

ance of the plus and minus signs in Holland. As the symbols for powers one finds here the notation of Grammatus, *N.*, *pri.*, *se.*, 3^a , 4^a , 5^a , etc., though occasionally, to fill out a space on a line, one en-

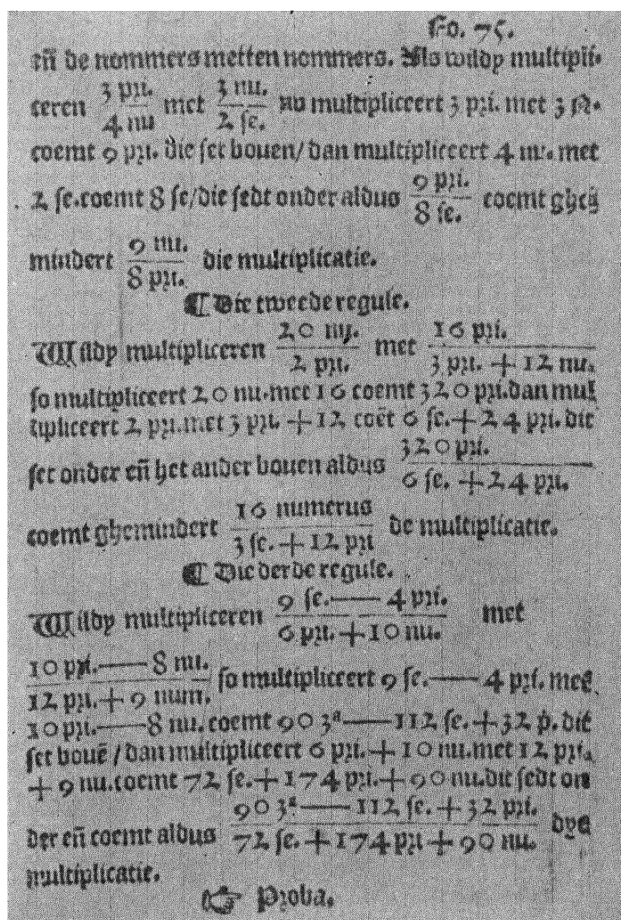

FIG. 60.—From Gielis van der Hoecke's *In arithmetica* (1537). Multiplication of fractions by *regule cos*.

counters *numerus*, *num.*, or *nu.* in place of *N.*; also *secu.* in place of *se.* For *pri.* he uses a few times *p*.

The translation of matter shown in Figure 60 is as follows: "[In order to multiply fractions simply multiply numerators by numera-

tors] and denominators by denominators. Thus, if you wish to multiply $\frac{3x}{4}$ by $\frac{3}{2x^2}$, you multiply $3x$ by 3 , this gives $9x$, which you write down. Then multiply 4 by $2x^2$, this gives $8x^2$, which you write under the other $\frac{9x}{8x^2}$. Simplified this becomes $\frac{9}{8x}$, the product. *Second rule:* If you wish to multiply $\frac{20}{2x}$ by $\frac{16x}{3x+12}$, multiply 20 by 16 [sic] which

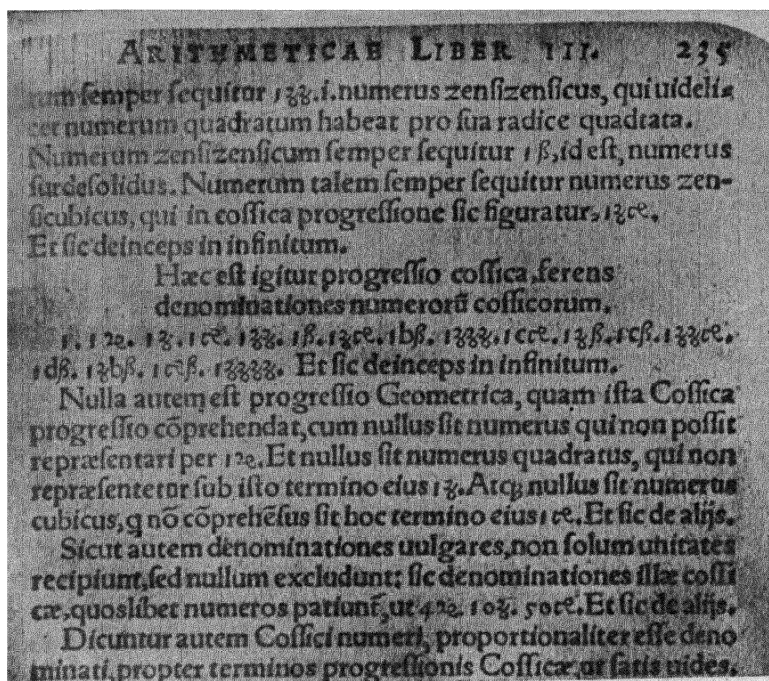

FIG. 61.—Part of a page from M. Stifel's *Arithmetica integra* (1544), fol. 235

gives $320x$, then multiply $2x$ by $3x+12$, which gives $6x^2+24x$. Place this under the other obtained above $\frac{320x}{6x^2+24x}$, this simplified gives:¹ $\frac{16}{3x^2+12x}$, the product. . . ."

As radical sign Gielis van der Hoecke does not use the German symbols of Rudolff, but the capital *R* of the Italians. Thus he writes (fol. 90B) " $6+R8$ " for $6+\sqrt{8}$, " $-R\ 32\ pri.$ " for $-\sqrt{32x}$.

¹ The numerator should be 160, the denominator $3x+12$.

GERMAN: MICHAEL STIFEL
(1544, 1545, 1553)

151. Figure 61 is part of a page from Michael Stifel's important work on algebra, the *Arithmetica integra* (Nürnberg, 1544). From the ninth and the tenth lines of the text it will be seen that he uses the same symbols as Rudolff had used to designate powers, up to and including x^9 . But Stifel carries here the notation as high as x^{16} . As Tropfke remarks,¹ the b in the symbol $b\beta$ of the seventh power leads Stifel to the happy thought of continuing the series as far as one may choose. Following the alphabet, his *Arithmetica integra* (1544) gives $c\beta = x^{11}$, $d\beta = x^{13}$, $e\beta = x^{17}$, etc.; in the revised *Coss* of Rudolff (1553), Stifel writes $\mathfrak{B}\beta$, $\mathfrak{C}\beta$, $\mathfrak{D}\beta$, $\mathfrak{G}\beta$. He was the first² who in print discarded the symbol for *dragma* and wrote a given number by itself. Where Rudolff, in his *Coss* of 1525 wrote 4ϕ , Stifel, in his 1553 edition of that book, wrote simply 4.

A multiplication from Stifel (*Arithmetica integra*, fol. 236v)³ follows:

$$\begin{array}{r} \text{[Concluding part "6}\frac{3}{4} + 8\mathcal{L} - 6} \\ \text{of a problem:] } 2\frac{3}{4} - 4 \\ \hline 12\frac{3}{4} + 16\mathfrak{C} - 12\frac{3}{4} \\ \quad - 24\frac{3}{4} - 32\mathcal{L} + 24 \\ \hline 12\frac{3}{4} + 16\mathfrak{C} - 36\frac{3}{4} - 32\mathcal{L} + 24 \text{ " } \end{array}$$

In Modern Symbols

$$\begin{array}{r} 6x^2 + 8x - 6 \\ 2x^2 - 4 \\ \hline 12x^4 + 16x^3 - 12x^2 \\ \quad - 24x^2 - 32x + 24 \\ \hline 12x^4 + 16x^3 - 36x^2 - 32x + 24 \end{array}$$

We give Stifel's treatment of the quartic equation, $1\frac{3}{4} + 2\mathfrak{C} + 6\frac{3}{4} + 5\mathcal{L} + 6$ *aequ.* 5550: "Quaeritur numerus ad quem additum suum quadratum faciat 5550. Pone igitur quod quadratum illud faciat $1A\frac{3}{4}$. tunc radix eius quadrata faciet $1A$. Et sic $1A\frac{3}{4} + 1A$. aequabitur

¹ *Op. cit.*, Vol. II, p. 120.

² Rudolff, *Coss* (1525), Signatur Hiiij (Stifel ed. [1553], p. 149); see Tropfke, *op. cit.*, Vol. II, p. 119, n. 651.

³ Treutlein, *op. cit.*, p. 39.

5550. Itacq $1A\frac{1}{2}$. acquabit $5550-1A$. Facit $1A$. 74. Ergo cum. $1\frac{1}{2}+2\frac{1}{2}+6\frac{1}{2}+5\frac{1}{2}+6$, aequetur. 5550. Sequitur quod. 74. aequetur $1\frac{1}{2}+1\frac{1}{2}+2$ Facit itacq. $1\frac{1}{2}$.¹

Translation:

$$x^4+2x^3+6x^2+5x+6=5,550.$$

Required the number which, when its square is added to it, gives 5,550. Accordingly, take the square, which it makes, to be A^2 . Then the square root of that square is A . Then $A^2+A=5,550$ and $A^2=5,550-A$. A becomes 74. Hence, since $x^4+2x^3+6x^2+5x+6=5,550$, it follows that $74=1x^2+x+2$ Therefore x becomes 8."

152. When Stifel uses more than the one unknown quantity \mathcal{X} , he at first follows Cardan in using the symbol q (abbreviation for *quantita*),² but later he represents the other unknown quantities by A, B, C In the last example in the book he employs five unknowns, \mathcal{X}, A, B, C, D . In the example solved in Figure 62 he represents the unknowns by \mathcal{X}, A, B . The translation is as follows:

"Required three numbers in continued proportion such that the multiplication of the [sum of] the two extremes and the difference by which the extremes exceed the middle number gives 4,335. And the multiplications of that same difference and the sum of all three gives 6,069.

$A+x$ is the sum of the extremes,

$A-x$ the middle number,

$2A$ the sum of all three,

$2x$ the difference by which the extremes exceed the

middle. Then $2x$ multiplied into the sum of the extremes, i.e., in $A+x$, yields $2xA+2x^2=4,335$. Then $2x$ multiplied into $2A$ or the sum of all make $4xA=6,069$.

"Take these two equations together. From the first it follows that $xA=\frac{4,335-2x^2}{2}$. But from the second it follows that $1xA=\frac{6,069}{4}$. Hence $\frac{4,335-2x^2}{2}=\frac{6,069}{4}$, for, since they are equal to one and the same, they are equal to each other. Therefore [by reduction] $17,340-8x^2=12,138$, which gives $x^2=650\frac{1}{4}$ and $x=25\frac{1}{2}$.

¹ *Arithmetica integra*, fol. 307 B.

² *Ibid.*, III, vi, 252A. This reference is taken from H. Bosmans, *Bibliotheca mathematica* (3d ser., 1906-7), Vol. VII, p. 66.

DE ARITHMET. CARDANI 313

Quarantur tres numeri continue proportionales, ita ut multiplicatio duorum extremorum, per differentiam, quam habent extremi simul, ultra numerum medium, faciant 4335. Et multiplicatio eiusdem differentiae, in summam omnium trium faciat 6069.

1 A + 1 2e. Est summa extremorum.

1 A — 1 2e. Est summa medij.

2 A. Est summa omnium trium.

2 2e. Est differentia quam habent extremi ultra mediū.

Itaq; 2 2e multiplicatae in summam extremorum, id est, in 1 A + 1 2e. faciunt, 2 2e A + 2 2e. aequata, 4335. Deinde 2 2e multiplicatae in 2 A seu in summam omnium, faciunt 4 2e A aequata 6069.

Confer iam duas aequationes illas. Nam ex priore sequitur quod 1 2e A faciat $4335 \frac{1}{2} \cdot 2e$. Ex posteriore autē sequitur quod 1 2e A. faciat $\frac{6069}{4}$. Sequitur ergo quod $4335 \frac{1}{2} \cdot 2e$ & $\frac{6069}{4}$ inter se aequentur. Quia quae uni & eidem sunt aequalia, etiam sibi inuicem sunt aequalia. Ergo (per reductionem) 17340 — 8 e aequantur. 12138. facit 12.650 $\frac{1}{4}$. Et 1 2e. facit 25 $\frac{1}{2}$.

Restat iam ut 1 A. etiam resoluatur, facit autem (ut paulo superius uidimus) 1 2e A. $\frac{6069}{4}$. Cum igitur duo illa inter se sint aequalia, Diuide utrunq; per 1 2e. tunc inuenies 1 A. aequari, seu facere. $\frac{6069}{42e}$. Cum autem 1 2e faciat 25 $\frac{1}{2}$. facient 42e. 102. Itaq; 6069. diuisa per 102. faciunt 59 $\frac{1}{2}$. Et tantum facit 1 A. Quare 1 A — 1 2e. id est, medius numerus facit 34. Et 1 A + 1 2e. id est, summa duorum extremorum facit 85. Iam igitur oritur noua quaestio haec.

Diuidantur 85 in duas partes, ita ut 34 mediet inter eas proportionaliter.

Sic stant numeri.

1 B. 34. 85 — 1 B.

Vnde 85 B — 1 B aequatur 156. facit 1 B 17. Et sic stant numeri exempli. 17. 34. 68.

KK

Excm

"It remains to find also $1A$. One has [as we saw just above] $1xA = \frac{6,069}{4}$. Since these two are equal to each other, divide each by x , and there follows $A = \frac{6,069}{4x}$. But as $x = 25\frac{1}{2}$, one has $4x = 102$, and 6,069 divided by 102 gives $59\frac{1}{2}$. And that is what A amounts to. Since $A - x$, i.e., the middle number equals 34, and $A + x$, i.e., the sum of the two extremes is 85, there arises this new problem:

"Divide 85 into two parts so that 34 is a mean proportional between them. These are the numbers:

$$B, \quad 34, \quad 85 - B.$$

Since $85B - B^2 = 1,156$, there follows $B = 17$. And the numbers of the example are 17, 34, 68."

Observe the absence of a sign of equality in Stifel, equality being expressed in words or by juxtaposition of the expressions that are equal; observe also the designation of the square of the unknown B by the sign B_3 . Notice that the fractional line is very short in the case of fractions with binomial (or polynomial) numerators—a singularity found in other parts of the *Arithmetica integra*. Another oddity is Stifel's designation of the multiplication of fractions.¹ They are written as we write ascending continued fractions. Thus

$$\frac{3}{4} \frac{2}{3} \frac{1}{2}$$

means "Tres quartae, duarum tertiarum, unius septimae," i.e., $\frac{3}{4}$ of $\frac{2}{3}$ of $\frac{1}{2}$.

The example in Fig. 62 is taken from the closing part of the *Arithmetica integra* where Cardan's *Ars magna*, particularly the solutions of cubic and quartic equations, receive attention. Of interest is Stifel's suggestion to his readers that, in studying Cardan's *Ars magna*, they should translate Cardan's algebraic statements into the German symbolic language: "Get accustomed to transform the signs used by him into our own. Although his signs are the older, ours are the more commodious, at least according to my judgment."²

¹ *Arithmetica integra* (1548), p. 7; quoted by S. Günther, *Vermischte Untersuchungen* (Leipzig, 1876), p. 131.

² *Arithmetica integra* (Nürnberg, 1544), Appendix, p. 306. The passage, as quoted by Tropske, *op. cit.*, Vol. II (2. ed.), p. 7, is as follows: "Assuescas, signa eius, quibus ipse utitur, transfigurare ad signa nostra. Quamvis enim signa quibus ipse utitur, uetustiora sint nostris, tamen nostra signa (meo quidē iudicio) illis sunt commodiora."

But he adopts Rudolff's dot notation for indicating the root of a binomial:¹

154. Apparently with the aim of popularizing algebra in Germany by giving an exposition of it in the German language, Stifel wrote in 1545 his *Deutsche arithmetica*³ in which the unknown x is expressed by *sum*, x^2 by “*sum: sum*,” etc. The nature of the book is indicated by the following equation:

⁴Treutlein, *op. cit.*, Vol. II, p. 34. For a facsimile reproduction of a page of Stifel's *Deutsche arithmetica*, see D. E. Smith, *Rara arithmetica* (1898), p. 234.

The inelegance of this notation results from an effort to render the subject easy; Stifel abandoned the notation in his later publications, except that the repetition of factors to denote powers reappears in 1553 in his "Cossische Progresz" (§ 156).

In this work of 1545 Stifel does not use the radical signs found in his *Arithmetica integra*; now he uses $\sqrt{}$, $\sqrt[3]{}$, $\sqrt[4]{}$, for square, cube, and fourth root, respectively. He gives (fol. 74) the German capital letter \mathfrak{M} as the sign of multiplication, and the capital letter \mathfrak{D} as the sign of division, but does not use either in the entire book.¹

155. In 1553 Stifel brought out a revised edition of Rudolff's *Coss*. Interesting is Stifel's comparison of Rudolff's notation of radicals with his own, as given at the end of page 134 (see Fig. 63a), and his declaration of superiority of his own symbols. On page 135 we read: "How much more convenient my own signs are than those of Rudolff, no doubt everyone who deals with these algorithms will notice for himself. But I too shall often use the sign $\sqrt{}$ in place of the $\sqrt[3]{}$, for brevity.

"But if one places this sign before a simple number which has not the root which the sign indicates, then from that simple number arises a surd number.

"Now my signs are much more convenient and clearer than those of Christoff. They are also more complete for they embrace all sorts of numbers in the arithmetic of surds. They are [here he gives the symbols in the middle of p. 135, shown in Fig. 63b]. Such a list of surd numbers Christoff's symbols do not supply, yet they belong to this topic.

"Thus my signs are adapted to advance the subject by putting in place of so many algorithms a single and correct algorithm, as we shall see.

"In the first place, the signs (as listed) themselves indicate to you how you are to name or pronounce the surds. Thus, $\sqrt[6]{}$ means the sursolid root of 6, etc. Moreover, they show you how they are to be reduced, by which reduction the declared unification of many (indeed all such) algorithms arises and is established."

156. Stifel suggests on folio 61B also another notation (which, however, he does not use) for the progression of powers of x , which he calls "die Cossische Progresz." We quote the following:

"Es mag aber die Cossische Progresz auch also verzeyhnet werden:

$$\begin{array}{ccccccc} 0 & 1 & 2 & 3 & 4 & & \\ 1 \cdot 1A \cdot 1AA \cdot 1AAA \cdot 1AAAA \cdot \text{etc.} \end{array}$$

¹ Cantor, *op. cit.*, Vol. II (2. ed., 1913), p. 444.

Item auch also:

0 1 2 3 4
1 · 1B · 1BB · 1BBB · 1BBBB · etc.

Item auch also:

0 1 2 3 4
1 · 1C · 1CC · 1CCC · 1CCCC · etc.

Vnd so fort an von andern Buchstaben."¹

years later. The product of two quantities, of which each is represented by a letter, is designated by juxtaposition.

GERMAN: NICOLAUS COPERNICUS

(1566)

157. Copernicus died in 1543. The quotation from his *De revolutionibus orbium coelestium* (1566; 1st ed., 1543)¹ shows that the exposition is devoid of algebraic symbols and is almost wholly rhetorical. We find a curious mixture of modes of expressing numbers: Roman numerals, Hindu-Arabic numerals, and numbers written out in words. We quote from folio 12:

"Circulum autem communi Mathematicorum consensu in CCCLX. partes distribuimus. Dimetientem uero CXX. partibus asciscebant prisci. At posteriores, ut scrupulorum cuitarent inuolutionem in multiplicationibus & diuisionibus numerorum circa ipsas lineas, quae ut plurimum incommensurabiles sunt longitudine, saepius etiam potentia, alij duodecies centena milia, alij uigesies, alij aliter rationalem constituerunt diametrum, ab eo tempore quo indiciae numerorum figurae sunt usu receptae. Qui quidem numerus quemcunque alium, sine Graecum, sine Latinum singulari quadam promptitudine superat, & omni generi supputationum aptissime sese accommodat. Nos quoq, eam ob causam accepimus diametri 200000. partes tanquam sufficientes, quae, possint errorem excludere patentem."

Copernicus does not seem to have been exposed to the early movements in the fields of algebra and symbolic trigonometry.

GERMAN: JOHANNES SCHEUBEL

(1545, 1551)

158. Scheubel was professor at the University of Tübingen, and was a follower of Stifel, though deviating somewhat from Stifel's notations. In Scheubel's arithmetic² of 1545 one finds the scratch method in division of numbers. The book is of interest because it does not use the + and - signs which the author used in his algebra; the + and - were at that time not supposed to belong to arithmetic proper, as distinguished from algebra.

¹ *Nicolai Copernici Torinensis de Revolutionibus Orbium Coelestium, Libri VI.* . . . Item, de Libris Revolutionum Nicolai Copernici Narratio prima, per M. Georgium Ioachimum Rheticum ad D. Ioan. Schonerum scripta. Basileae (date at the end of volume, M.D.LXVI).

² *De Numeris et Diversis Rationibus seu Regulis computationum Opusculum, a Ioanne Scheubelio compositum . . .* (1545).

Scheubel in 1550 brought out at Basel an edition of the first six books of Euclid which contains as an introduction an exposition of algebra,¹ covering seventy-six pages, which is applied to the working of examples illustrating geometric theorems in Euclid.

159. Scheubel begins with the explanation of the symbols for powers employed by Rudolff and Stifel, but unlike Stifel he retains a symbol for *numerus* or *dragma*. He explains these symbols, up to the twelfth power, and remarks that the list may be continued indefinitely. But there is no need, he says, of extending this unwieldy designation, since the ordinal natural numbers afford an easy nomenclature. Then he introduces an idea found in Chuquet, Grammateus, and others, but does it in a less happy manner than did his predecessors. But first let us quote from his text. After having explained the symbol for *dragma* and for x he says (p. 2): "The third of them \mathfrak{z} , which, since it is produced by multiplication of the *radix* into itself, and indeed the first [multiplication], is called the *Prima* quantity and furthermore is noted by the syllable *Pri*. Even so the fourth \mathfrak{c} , since it is produced secondly by the multiplication of that same *radix* by the square, i.e., by the *Prima* quantity, is called the *Second* quantity, marked by the syllable *Se*. Thus the fifth sign \mathfrak{zz} , which springs thirdly from the multiplication of the *radix*, is called the *Tertia* quantity, noted by the syllable *Ter*. . . ."² And so he introduces the series of symbols, *N.*, *Ra.*, *Pri.*, *Se.*, *Ter.*, *Quar.*, *Quin.*, *Sex.*, *Sep.* . . . , which are abbreviations for the words *numerus*, *radix*, *prima quantitas* (because it arises from one multiplication), *secunda quantitas* (because it arises from two multiplications), and so on. This scheme gives rise to the oddity of designating x^n by the number $n-1$, such as we have not hitherto encountered. In Pacioli one finds the contrary relation, i.e., the designation of x^{n-1} by x^n (§ 136). Scheubel's notation does not coincide with that of Grammateus, who more judiciously had used *pri.*, *se.*, etc., to designate x , x^2 , etc. (§ 147). Scheubel's singular notation is illustrated by

¹ *Euclidis Megarensis, Philosophi et Mathematici excellentissimi, sex libri priores de Geometricis principijs, Graeci et Latini . . . Algebrae porro regylae, propter numerorum exempla, passim propositionibus adiecta, his libris praemissae sunt, cadenque demonstratae. Aulhore Ioanne Scheubelio, . . . Basileae (1550). I used the copy belonging to the Library of the University of Michigan.*

² "Tertius de, \mathfrak{z} . qui cū ex multiplicatione radicis in se producat, et primo quidem: Prima quantitas, et *Pri* etiam syllaba notata, appelletur. Quartus uerò \mathfrak{c} quia ex multiplicatione eiusdem radicis cum quadrato, hoc est, cum prima quantitate, secundò producitur: *Se* syllaba notata, Secunda quantitas dicitur. Sic character quintus, \mathfrak{zz} , quia ex multiplicatione radicis cum secunda quantitate tertio nascitur: *Ter* syllaba notata, Tertia etiam quantitas dicitur. . . ."

Figure 64, where he shows the three rules for solving quadratic equations. The first rule deals with the solution of $4x^2+3x=217$, the second with $3x+175=4x^2$, the third with $3x^2+217=52x$. These different cases arose from the consideration of algebraic signs, it being desired that the terms be so written as to appear in the positive form. Only positive roots are found.

FIG. 64.—Part of p. 28 in Scheubel's Introduction to his *Euclid*, printed at Basel in 1550.

Under proportion we quote one example (p. 41):

“ 3 ra. + 4 N. ualent 8 se. + 4 pri.
 quanti 8 ter. — 4 ra.
 64 sex. + 32 quin. — 32 ter. — 16 se.
 Facit ————— ”
 3 ra. + 4 N.

In modern notation:

$$\begin{array}{r} 3x+4 \text{ are worth } 8x^3+4x^2 \\ \text{how much } 8x^4-4x \text{ .} \\ 64x^7+32x^6-32x^4-16x^3 \\ \text{Result } \hline 3x+4 \end{array} .$$

In the treatment of irrationals or *numeri surdi* Scheubel uses two notations, one of which is the abbreviation *Ra.* or *ra.* for *radix*, or "square root," *ra.cu.* for "cube root," *ra.ra.* for "fourth root." Confusion from the double use of *ra.* (to signify "root" and also to signify x) is avoided by the following implied understanding: If *ra.* is followed by a number, the square root of that number is meant; if *ra.* is preceded by a number, then *ra.* stands for x . Thus "8 *ra.*" means $8x$; "*ra.* 12" means $\sqrt{12}$.

Scheubel's second mode of indicating roots is by Rudolff's symbols for square, cube, and fourth roots. He makes the following statement (p. 35) which relates to the origin of $\sqrt{}$: "Many, however, are in the habit, as well they may, to note the desired roots by their points with a stroke ascending on the right side, and thus they prefix for the square root, where it is needed for any number, the sign $\sqrt{}$: for the cube root, $\sqrt[3]{}$; and for the fourth root $\sqrt[4]{}$."¹ Both systems of notation are used, sometimes even in the same example. Thus, he considers (p. 37) the addition of "*ra.* 15 *ad ra.* 17" (i.e., $\sqrt{15} + \sqrt{17}$) and gives the result "*ra.col.* 32 + $\sqrt{1020}$ " (i.e. $\sqrt{32 + \sqrt{1,020}}$). The *ra.col.* (*radix collecti*) indicates the square root of the binomial. Scheubel uses also the *ra.re* (*radix residui*) and *radix binomij*. For example (p. 55), he writes "*ra.re.* $\sqrt{15} - \sqrt{12}$ " for $\sqrt{\sqrt{15} - \sqrt{12}}$. Scheubel suggests a third notation for irrationals (p. 35), of which he makes no further use, namely, *radix se.* for "cube root," the abbreviation for *secundae quantitatis radix*.

The algebraic part of Scheubel's book of 1550 was reprinted in 1551 in Paris, under the title *Algebrae compendiosa facilisque descriptio*.²

¹ "Solent tamen multi, et bene etiam, has desideratas radices, suis punctis cum lines quadam à dextro latere ascendente, notare, atque sic pro radice quidem quadrata, ubi haec in aliquo numero desideratur, notam $\sqrt{}$: pro cubica uerò, $\sqrt[3]{}$: ac radicis radice deinde, $\sqrt[4]{}$ praeponunt."

² Our information on the 1551 publication is drawn from H. Staigmüller, "Johannes Scheubel, ein deutscher Algebraiker des XVI. Jahrhunderts," *Abhandlungen zur Geschichte der Mathematik*, Vol. IX (Leipzig, 1899), p. 431-69; A. Witting and M. Gebhardt, *Beispiele zur Geschichte der Mathematik*, II. Teil

It is of importance as representing the first appearance in France of the symbols $+$ and $-$ and of some other German symbols in algebra.

Charles Hutton says of Scheubel's *Algebrae compendiosa* (1551): "The work is most beautifully printed, and is a very clear though succinct treatise; and both in the form and matter much resembles a modern printed book."¹

MALTESE: WIL. KLEBITIUS

(1565)

160. Through the courtesy of Professor H. Bosmans, of Brussels, we are able to reproduce a page of a rare and curious little volume containing exercises on equations of the first degree in one unknown number, written by Wilhelm Klebitius and printed at Antwerp in 1565.² The symbolism follows Scheubel, particularly in the fancy form given to the plus sign. The unknown is represented by "1R."

The first problem in Figure 65 is as follows: Find a number whose double is as much below 30,000 as the number itself is below 20,000. In the solution of the second and third problems the notational peculiarity is that $\frac{1}{3}R. - \frac{1}{8}$ is taken to mean $\frac{1}{3}R. - \frac{1}{8}R.$, and $1R. - \frac{5}{8}$ to mean $1R. - \frac{5}{8}R.$

GERMAN: CHRISTOPHORUS CLAVIUS

(1608)

161. Though German, Christophorus Clavius spent the latter part of his life in Rome and was active in the reform of the calendar. His *Algebra*³ marks the appearance in Italy of the German $+$ and $-$ signs, and of algebraic symbols used by Stifel. Clavius is one of the very first to use round parentheses to express aggregation. From his *Algebra* we quote (p. 15): "Plerique auctores pro signo $+$ ponunt literam P , vt significet plus: pro signo vero $-$ ponunt literam M , vt significet minus. Sed placet nobis vti nostris signis, vt à literis distinguantur, ne confusio oriatur." Translation: "Many authors put in place of the sign $+$ the letter P , which signifies "plus":

(Leipzig-Berlin, 1913), p. 25; Tropicke, *op. cit.*, Vol. I (1902), p. 195, 198; Charles Hutton, *Tracts on Mathematical and Philosophical Subjects*, Vol. II (London, 1812), p. 241-43; L. C. Karpinski, *Robert of Chester's . . . Al-Khowarizmi*, p. 39-41.

¹ Charles Hutton, *op. cit.*, p. 242.

² The title is *Insulae Melitensis, quam alias Mallam vocant, Historia, quaestionib. aliquot Mathematicis reddita iucundior*. At the bottom of the last page: "*Avth. Wil. Kebutio.*"

³ *Algebra Christophori Clavii Bambergensis e Societate Iesv.* (Romae, M.DC.VIII).

likewise, for the sign — they put the letter *M*, which signifies “minus.” But we prefer to use our signs; as they are different from letters, no confusion arises.”

In his arithmetic, Clavius has a distinct notation for “fractions of fractional numbers,” but strangely he does not use it in the ordinary

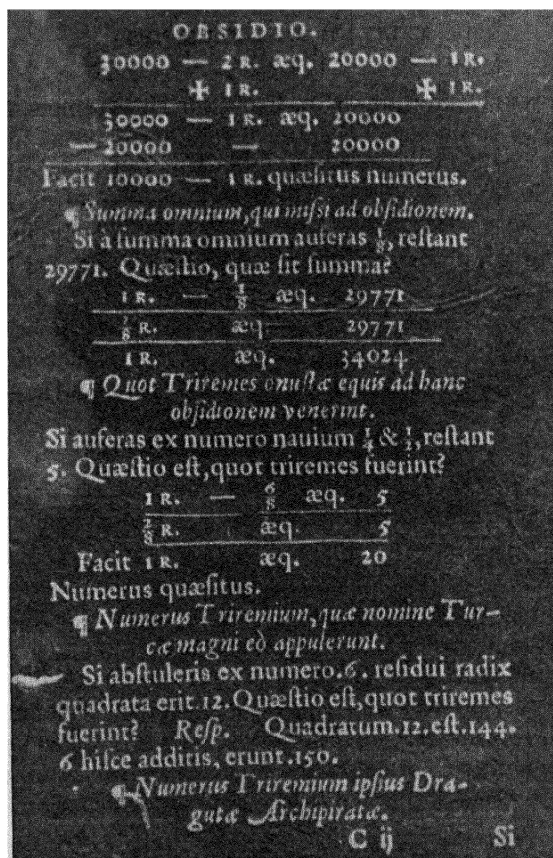

FIG. 65.—Page from W. Klebitius (1565)

multiplication of fractions. His $\frac{3}{4} \cdot \frac{1}{4}$ means $\frac{3}{4}$ of $\frac{1}{4}$. He says: “Vt prædicta minutia minutiae ita scribenda est $\frac{3}{4} \cdot \frac{1}{4}$ pronuntiaturque sic. Tres quintae quatuor septimarū vnus integri.”¹ Similarly, $\frac{3}{4} \cdot \frac{3}{4} \cdot \frac{1}{6} \cdot \frac{1}{2}$ yields $\frac{1}{144}$. The distinctive feature in this notation is the

¹ *Epitome arithmeticae* (Rome, 1583), p. 68; see also p. 87.

omission of the fractional line after the first fraction.¹ The dot cannot be considered here as the symbol of multiplication. No matter what the operation may be, all numbers, fractional or integral, in the

C A P. XXVIII. 159

Sit rursus Binomium primum $72 + \sqrt{8} 2880$. Maius nomen 72 . fecabitur in duas partes producentes 720 . quartam partem quadrati 2880 . maioris nominis, hac ratione.

Semis sis maioris nominis 72 . est 36 . a cuius quadrato 1296 . detracta quarta pars prædicta 720 . relinquit 576 . cuius radix 24 . addita ad semissem nominatam 36 . & detracta ab eadem, facit partes quæsitæ 60 . & 12 . Ergo radix Binomij est $\sqrt{8} 60 + \sqrt{8} 12$. quod hic probatum est per multiplicationem radicis in se quadratè.

FIG. 66.—A page in Clavius' *Algebra* (Rome, 1608). It shows one of the very earliest uses of round parentheses to express aggregation of terms.

arithmetic of Clavius are followed by a dot. The dot made the numbers stand out more conspicuously.

¹ In the edition of the arithmetic of Clavius that appeared at Cologne in 1601, p. 88, 126, none of the fractional lines are omitted in the foregoing passages.

As symbol of the unknown quantity Clavius uses¹ the German \mathcal{X} . In case of additional unknowns, he adopts $1A$, $1B$, etc., but he refers to the notation $1q$, $2q$, etc., as having been used by Cardan, Nonius, and others, to represent unknowns. He writes: $3\mathcal{X} + 4A$, $4B - 3A$ for $3x + 4y$, $4z - 3y$.

Clavius' *Astrolabium* (Rome, 1593) and his edition of the last nine books of *Euclid* (Rome, 1589) contain no algebraic symbolism and are rhetorical in exposition.

BELGIUM: SIMON STEVIN

(1585)

162. Stevin was influenced in his notation of powers by Bombelli, whose exponent placed in a circular arc became with Stevin an exponent inside of a circle. Stevin's systematic development of decimal fractions is published in 1585 in a Flemish booklet, *La thiende*,² and also in French in his *La disme*. In decimal fractions his exponents may be interpreted as having the base one-tenth. Page 16 (in Fig. 67) shows the notation of decimal fractions and the multiplication of 32.57 by 89.46, yielding the product 2913.7122. The translation is as follows:

"III. *Proposition, on multiplication*: Being given a decimal fraction to be multiplied, and the multiplier, to find their product.

"*Explanation of what is given*: Let the number to be multiplied be 32.57, and the multiplier 89.46. *Required*, to find their product. *Process*: One places the given numbers in order as shown here and multiplies according to the ordinary procedure in the multiplication of integral numbers, in this wise: [see the multiplication].

"Given the product (by the third problem of our *Arithmetic*) 29137122; now to know what this means, one adds the two last of the given signs, one (2) and the other (2), which are together (4). We say therefore that the sign of the last character of the product is (4), the which being known, all the others are marked according to their successive positions, in such a manner that 2913.7122 is the required product. *Proof*: The given number to be multiplied 32.57 (according to the third definition) is equal to $32_{10}^{\frac{5}{10}} \cdot 10_{10}^{\frac{7}{10}}$, together $32_{10}^{\frac{5}{10}} 7_{10}^{\frac{7}{10}}$. And for the same reason the multiplier 89.46 becomes $89_{10}^{\frac{4}{10}} 6_{10}^{\frac{6}{10}}$. Multiplying the said $32_{10}^{\frac{5}{10}} 7_{10}^{\frac{7}{10}}$ by the same, gives a product (by the twelfth problem of our *Arithmetic*) $2913_{10}^{\frac{7}{10}} 13_{10}^{\frac{2}{10}} 2_{10}^{\frac{2}{10}}$; but this same value has also the said product 2913.7122; this is therefore the correct product, which we

¹ *Algebra*, p. 72.

² A facsimile edition of *La "thiende"* was brought out in 1924 at Anvers by H. Bosmans.

were to prove. But let us give also the reason why ② multiplied by ②, gives the product ④ (which is the sum of their numbers), also why ④ times ⑤ gives the product ⑨, and why ③ times ③ gives ⑥, etc. We take $\frac{1}{10}$ and $\frac{3}{10}$ (which by the third definition of this Disme are .2 and .03; their product is $\frac{6}{1000}$ which, according to our third definition, is equal to .006. Multiplying, therefore, ① by ② gives the

FIG. 67.—Two pages in S. Stevin's *Thiende* (1585). The same, in French, is found in *Les œuvres mathématiques de Simon Stevin* (ed. A. Girard; Leyden, 1634), p. 209.

product ③, a number made up of the sum of the numbers of the given signs. *Conclusion:* Being therefore given a decimal number as a multiplicand, and also a multiplier, we have found their product, as was to be done.

Note: If the last sign of the numbers to be multiplied is not the same as the sign of the last number of the multiplier, if, for example, the one is 3④7①8②, and the other 5①4②, one proceeds as above

and the disposition of the characters in the operation is as shown: [see process on p. 17]."

A translation of the *La disme* into English was brought out by Robert Norman at London in 1608 under the title, *Disme: The Art of*

QUESTION XX.

Trouvons un \odot tel, que son quarré — 12 multiplié par la somme du double d'icelui \odot , & le quarré de — 2 & 4, le produit soit egal au quarré du produit de — 2 par icelui \odot requis.

CONSTRUCTION.

Soit le nombre requis	1 \odot	4
Son quarré 1 \odot^2 , auquel ajousté — 12		
faict	1 \odot^2 — 12	4
Qui multiplié par la somme du double du nombre requis, & le quarré de — 2 & 4, qui est		
par 2 \odot + 8, faict 2 \odot^3 + 8 \odot^2 — 24 \odot — 96		64
Egal au quarré du produit de — 2, par 1 \odot		
premier en l'ordre, qui est à	4 \odot^2	

Lesquels reduits, 1 \odot^3 sera egale à — 2 \odot^2 + 12 \odot + 48; Et 1 \odot par le 71 probleme, vaudra 4.

Je di que 4 est le nombre requis. *Demonstration.* Le quarré de 4 est 16, qui avec — 12 faict 4, qui multiplié par 16 (16 pour la somme du double d'iceluy 4, & le quarré de — 2 & encore 4) faict 64, qui sont egales au quarré du produit de — 2, par le 4 trouvé, selon le requis; ce qu'il falloit demonstrez.

QVE.

FIG. 68.—From p. 98 of *L'arithmétique* in Stevin's *Œuvres mathématiques* (Leyden, 1634).

Tenths, or Decimall Arithmetike. Norman does not use circles, but round parentheses placed close together, the exponent is placed high, as in $(^2)$. The use of parentheses instead of circles was doubtless typographically more convenient.

Stevin uses the circles containing numerals also in algebra. Thus

a circle with 1 inside means x , with 2 inside means x^2 , and so on. In Stevin's *Œuvres* of 1634 the use of the circle is not always adhered to. Occasionally one finds, for x^4 , for example,¹ the signs (4) and (4).

The translation of Figure 68 is as follows: "To find a number such that if its square -12 , is multiplied by the sum of double that number and the square of -2 or 4 , the product shall be equal to the square of the product of -2 and the required number.

Solution

"Let the required number be	x	4
Its square x^2 , to which is added -12 gives $x^2 - 12$		4
This multiplied by the sum of double the required number and the square of -2 or 4 , i.e., by $2x + 8$, gives $2x^3 + 8x^2 - 24x - 96$ equal to the square of the product of -2 and x , i.e., equal to . . . $4x^2$ Which reduced, $x^3 = -2x^2 + 12x + 48$; and x , by the problem 71, becomes 4. I say that 4 is the required number.		64

"*Demonstration*: The square of 4 is 16, which added to -12 gives 4, which multiplied by 16 (16 being the sum of double itself 4, and the square of -2 or 4) gives 64, which is equal to the square of the product of -2 and 4, as required; which was to be demonstrated."

If more than one unknown occurs, Stevin marks² the first unknown "1⊙," the second "1 *secund.* ⊙," and so on. In solving a Diophantine problem on the division of 80 into three parts, Stevin represents the first part by "1⊙," the second by "1 *secund.* ⊙," the third by " $-① - 1$ *secund.* ① + 80." The second plus $\frac{1}{5}$ the first + 6 minus the binomial $\frac{1}{5}$ the second + 7 yields him " $\frac{8}{5}$ *secund.* ⊙ + $\frac{1}{5}$ ⊙ $- 1$." The sum of the third and $\frac{1}{5}$ the second, + 7, minus the binomial $\frac{1}{5}$ the third + 8 yields him " $\frac{8}{5}$ ⊙ $- \frac{3}{5}$ *secund.* ⊙ + $\frac{4}{5}$ ①." By the conditions of the problem, the two results are equal, and he obtains "1 *Secund.* ⊙ *Aequalem* $- \frac{1}{5}$ $\frac{1}{5}$ ⊙ + 45." In his *L'arithmétique*³ one finds "12 *sec.* ④ + 23① *M sec.* ② + 10②," which means $12y^4 + 23xy^2 + 10x^2$, the *M* signifying here "multiplication" as it had with Stifel (§ 154). Stevin uses also *D* for "division."

163. For radicals Stevin uses symbols apparently suggested by

¹ *Les Œuvres mathématiques de Simon Stevin* (1634), p. 83, 85.

² Stevin, *Tomus Quintus mathematicorum Hypomnematum de Miscellaneis* (Leiden, 1608), p. 516.

³ Stevin, *Œuvres mathématiques* (Leyden, 1634), p. 60, 91, of "Le II. livre d'arith."

those of Christoff Rudolff, but not identical with them. Notice the shapes of the radicals in Figure 69. One stroke yields the usual square root symbol $\sqrt{}$, two strokes indicate the fourth root, three strokes the eighth root, etc. Cube root is marked by $\sqrt{}$ followed by a 3 inside a circle; $\sqrt[3]{}$ followed by a 3 inside a circle means the cube root twice taken, i.e., the ninth root. Notice that $\sqrt{3}\chi(2)$ means $\sqrt{3}$ times x^2 , not $\sqrt{3x^2}$; the χ is a sign of separation of factors. In place of the u or v to express "universal" root, Stevin uses *bin* ("binomial") root.

Stevin says that $\frac{3}{2}$ placed within a circle means $x^{\frac{3}{2}}$, but he does not actually use this notation. His words are (p. 6 of *Œuvres* [*Arithmetic*]), " $\frac{3}{2}$ en un circle seroit le caractere de racine quarrée de (3), par ce que telle $\frac{3}{2}$ en circle multipliée en soy donne produit (3), et ainsi des autres." A notation for fractional exponents had been suggested much earlier by Oresme (§ 123).

LORRAINE: ALBERT GIRARD

(1629)

164. Girard¹ uses + and −, but mentions ÷ as another sign used for "minus." He uses = for "difference entre les quantitez où il se treuve." He introduces two new symbols: *ff*, *plus que*; §, *moins que*. In further explanation he says: "Touchant les lettres de l'Alphabet au lieu des nombres: soit *A* & aussi *B* deux grandeurs: la somme est $A+B$, leur difference est $A-B$, (ou bien si *A* est majeur on dira que c'est $A-B$) leur produit est AB , mais divisant *A* par *B* viendra $\frac{A}{B}$ comme és fractions: les voyelles se posent pour les choses incognues." This use of the vowels to represent the unknowns is in line with the practice of Vieta.

The marks (2), (3), (4), . . . , indicate the second, third, fourth, . . . , powers. When placed before, or to the left, of a number, they signify the respective power of that number; when placed after a number, they signify the power of the unknown quantity. In this respect Girard follows the general plan found in Schöner's edition of the *Algebra* of Ramus. But

BRIEFVE COLLECTION DES
CHARACTERES Q'ON VSERA EN
CESTE ARITHMETIQUE.

Veu que la cognoissance des caracteres est de grande consequence, par ce qu'on les use en l'Arithmetique au lieu des mots, nous les ajouterons icy, (combien qu'au precedent chacun a este amplement declare

[Continued on page 159]

¹ *Invention nouvelle en l'Algebre, A Amsterdam* (M.DC.XXIX); reimpression par Dr. D. Bierens de Haan (Leiden, 1884), fol. B.

Girard adopts the practice of Stevin in using fractional exponents. Thus, " $(\frac{3}{4})49$ " means $(\sqrt[4]{49})^3 = 343$, while " $49(\frac{3}{4})$ " means $49x^{\frac{3}{4}}$. He points out that 18(0) is the same as 18, that (1)18 is the same as 18(0).

We see in Girard an extension of the notations of Chuquet, Bombelli, and Stevin; the notations of Bombelli and Stevin are only variants of that of Chuquet.

The conflict between the notation of roots by the use of fractional exponents and by the use of radical signs had begun at the time of Girard. "Or pource que $\sqrt{\quad}$ est en usage, on le pourra prendre au lieu de $(\frac{1}{2})$ à cause aussi de sa facilité, signifiant racine seconde, ou racine quarée; que si on veut poursuivre la progression on pourra au lieu de $\sqrt{\quad}$ marker $\sqrt[3]{\quad}$; & pour la racine cubique, ou tierce, ainsi $\sqrt[4]{\quad}$ ou bien $(\frac{1}{4})$, ou bié \mathcal{C} , ce qui peut estre au choix, mais pour en dire mon opinion les fractions sont plus expresses & plus propres à exprimer en perfection, & $\sqrt{\quad}$ plus faciles et expedientes, comme $\sqrt[3]{32}$ est à dire la racine de 32, & est 2. Quoy que ce soit l'un & l'autre sont faciles

à comprendre, mais $\sqrt{\quad}$ et \mathcal{C} sont pris pour facilité." Girard appears to be the first to suggest placing the index of the root in the opening of the radical sign, as $\sqrt[3]{\quad}$. Sometimes he writes $\sqrt{\sqrt{\quad}}$ for $\sqrt[4]{\quad}$.

en la definition) par ordie tous ensemble cōme s'ensuit.

Les caractères signifiāns quantitez, desquels l'explication se trouve es 14. 15. 16. 17. 18. definitions, sont tels.

⑥ Commencement de quantite qui est nombre Arith. ou radical quelconque.

① prime quantite.
② seconde quantite.
③ tierce quantite.
④ quarte quantite, &c.

Les caractères signifiāns postposees quantitez, desquels l'explication se trouve à la 28 definition, sont tels:

1 sec. ① Vne prime quantite secondement posee.
4 ter. ② Quatre secondes quantitez tiercement posees, ou procedans de la prime quantite tiercement posee.

1 ① sec. ① Produit d'une prime quantite par une prime quantite secondement posee.
5 ① ter. ③ Produit de cinq quartes quantitez par une seconde quantite tiercement posee.

Les caractères signifiāns racine de quels l'explication se trouve à la 29 & 30 definition, sont tels:

✓ Racine de quarré.
✓✓ Racine de racine de quarré.
✓✓✓ Racine de racine de racine de quarré.
✓✓✓✓ Racine de racine de racine de racine de quarré.
✓③ Racine de cube.
✓④ Racine de racine de cube.
✓④ Racine de quarte quantite.
✓④ Racine de racine de quarte quantite, &c.

Le caractère signifiant la separation entre le signe de racine & la quantite, duquel l'explication se trouve à la 34. definition, est tel.

X, Comme ✓ 3 X ② n'est pas le mesme que ✓ 3 ②, comme dict est à ladicte 34. definition.

Les caractères signifiāns plus & moins, comme à la 36 definition, sont tels:

+ Plus.
- Moins.

Et pour expliquer la racine d'un multinomie (qu'aucuns appellent racine universelle) nous userons le vocable du multinomie, comme:

✓ bino 2 + ✓ 3, c'est à dire racine quarrée de binomie, ou de la somme de 2 & ✓ 3.
✓ trino ✓ 3 + ✓ 2 - ✓ 5, c'est à dire racine quarrée de trinomie, ou de la somme de ✓ 3 & ✓ 2 & - ✓ 5.
✓③ bino ✓ 2 + ✓ 3, c'est à dire racine cubique de binomie ✓ 2 + ✓ 3.
✓ bino 2 c'est à dire racine quarrée de binomie 2.
✓③ bino 2 ③ + 1 ①, c'est à dire racine cubique de binomie 2 ③ + 1 ①, &c.

FIG. 69.—From S. Stevin's *L'arithmétique* in *Œuvres mathématiques* (ed. A. Girard; Leyden, 1634), p. 19.

The book contains other notations which are not specially explained. Thus the cube of $B+C$ is given in the form $B(B_q+C_q)+C(B_q+C_q)$.

We see here the use of round parentheses, which we encountered before in the *Algebra* of Clavius and, once, in Cardan. Notice also that C_q^3 means here $3C^2$.

Autre exemple

"Soit 1(3) esgale à $-6(1)+20$

Divisons tout par 1(1)

1(2) esgale à $-6+\frac{20}{1(1)}$."

In Modern Symbols

Let $x^3 = -6x + 20$

Divide all by x ,

$x^2 = -6 + \frac{20}{x}$.

Again (fol. F3): "Soit 1(3) esgale à $12(1)-18$ (impossible d'estre esgal)
 car le $\frac{1}{3}$ est 4 9 qui est $\frac{1}{3}$ de 18
 son cube 64 81 son quarré.
 Et puis que 81 est plus que 64, l'equation est impossible & inepte."

Translation: "Let $x^3 = 12x - 18$ (impossible to be equal)
 because the $\frac{1}{3}$ is 4 9 which is $\frac{1}{3}$ of 18
 its cube 64 81 its square
 And since 81 is more than 64, the equation is impossible and inept."

A few times Girard uses parentheses also to indicate multiplication (see *op. cit.*, folios C_3^b , D_3^a , F_4^b).

GERMAN-SPANISH: MARCO AUREL
(1552)

165. Aurel states that his book is the first algebra published in Spain. He was a German, as appears from the title-page: *Libro primero de Arithmetica Algebratica ... por Marco Aurel, natural Aleman* (Valencia, 1552).¹ It is due to his German training that German algebraic symbols appear in this text published in Spain. There is hardly a trace in it of Italian symbolism. As seen in Figure 70, the plus (+) and minus (−) signs are used, also the German symbols for powers of the unknown, and the clumsy Rudolffian symbols for roots of different

¹ Aurel's algebra is briefly described by Julio Rey Pastor, *Los matemáticos españoles del siglo XVI* (Oviedo, 1913), p. 36 n.; see *Bibliotheca mathematica*, Vol. IV (2d ser., 1890), p. 34.

orders. In place of the dot, used by Rudolff and Stifel, to express the root of a polynomial, Aurel employs the letter *v*, signifying universal root or *rayz vniuersal*. This *v* is found in Italian texts.

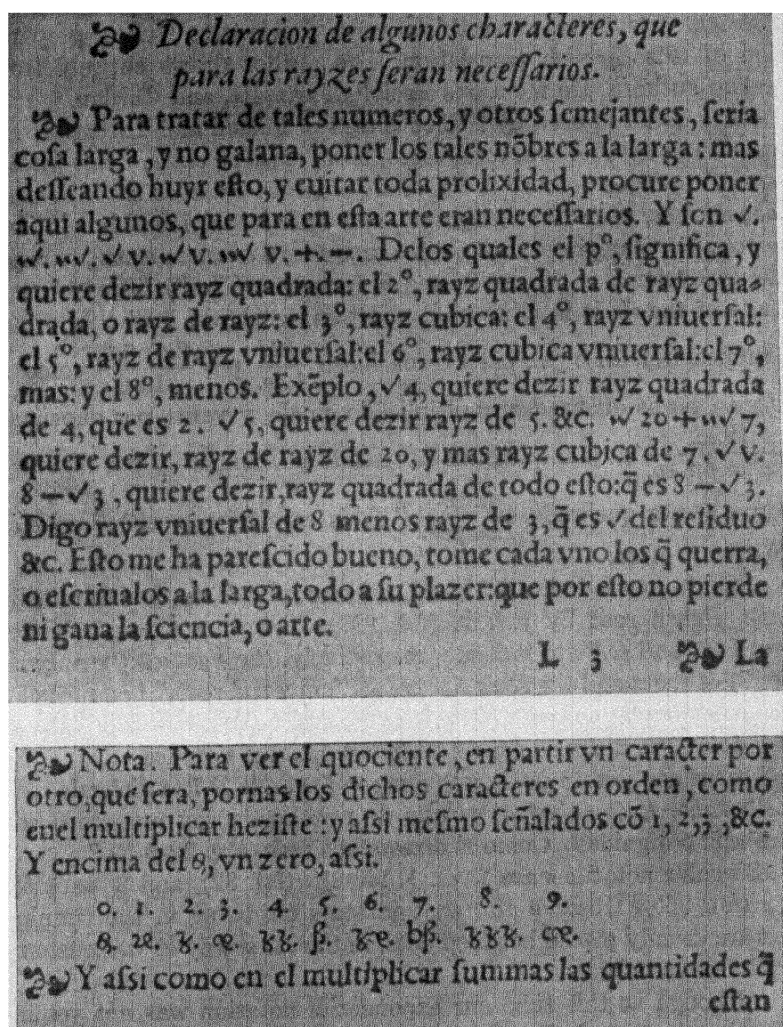

FIG. 70.—From Aurel's *Arithmetica algebrica* (1552). (Courtesy of the Library of the University of Michigan.) Above is part of fol. 43, showing the + and −, and the radical signs of Rudolff, also the $\sqrt{}$. Below is a part of fol. 73B, containing the German signs for the powers of the unknown and the sign for a given number.

PORTUGUESE-SPANISH: PEDRO NUÑEZ

(1567)

166. Nuñez' *Libro de algebra* (1567)¹ bears in the Dedication the date December 1, 1564. The manuscript was first prepared in the Portuguese language some thirty years previous to Nuñez' preparation of this Spanish translation. The author draws entirely from Italian authors. He mentions Pacioli, Tartaglia, and Cardan.

The notation used by Nuñez is that of Pacioli and Tartaglia. He uses the terms *Numero, cosa, censo, cubo, censo de censo, relato primo, censo de cubo* or *cubo de censo, relato segundo, censo de censo de cẽso, cubo de cubo, censo de relato primo*, and their respective abbreviations *co., ce., cu., ce.ce., re.pº, ce.cu. or cu.ce., re.segº. ce.ce.ce., cu.cu., ce.re.pº*. He uses \tilde{p} for *más* ("more"), and \tilde{m} for *menos* ("les"). The only use made of the ✱ is in cross-multiplication, as shown in the following sentence (fol. 41): "... partiremos luego $\frac{12.}{1.co.}$ por $\frac{2.cu.\tilde{p}.8.}{1.ce.}$ como si fuessen puros quebrados, multiplicãdo en ✱, y verna por quociente $\frac{12.ce.}{2.ce.ce.\tilde{p}.8.co.}$ el qual quebrado abreuiado por numero y por dignidad verna a este quebrado $\frac{6.co.}{1.cu.\tilde{p}.4.}$." This expression, *multiplicando en* ✱, occurs often.

Square root is indicated by *R.*, cube root by *R.cu.*, fourth root by *R.R.*, eighth root by *R.R.R.* (fol. 207). Following Cardan, Nuñez uses *L.R.* and *R.V.* to indicate, respectively, the *ligatura* ("combination") of roots and the *Raiz vniuersal* ("universal root," i.e., root of a binomial or polynomial). This is explained in the following passage (fol. 45b): "... diciendo assi: *L.R.7\tilde{p}R.4.\tilde{p}.3.* que significa vna quantidad sorda compuesta de .3. y 2. que son 5. con la *R.7.* o diciendo assi: *L.R.3\tilde{p}2.co.* *Raiz vniuersal* es raiz de raiz ligada con numero o con otra raiz o dignidad. Como si dixessemos assi: *R.v. 22 \tilde{p} R.9.*"

Singular notations are 2. *co.* $\frac{1}{4}$. for $2\frac{1}{4}x$ (fol. 32), and 2. *co.* $\frac{2}{3}$ for $2\frac{2}{3}x$ (fol. 36b). Observe also that integers occurring in the running text are usually placed between dots, in the same way as was customary in manuscripts.

Although at this time our exponential notation was not yet invented and adopted, the notion of exponents of powers was quite well understood, as well as the addition of exponents to form the product

¹ *Libro de Algebra en arithmetica y Geometria. Compuesto por el Doctor Pedro Nuñez, Cosmographo Mayor del Rey de Portugal, y Cathedratico Jubilado en la Cathedra de Mathematicas en la Vniuersidad de Coymbra* (En Anvers, 1567).

of terms having the same base. To show this we quote from Nuñez the following (fol. 26b):

"... si queremos multiplicar .4. co. por .5. ce. diremos asi .4. por .5. hazen .20. y porque .1. denominaciõ de co. sũmado con .2. denominacion de censo hazen .3. que es denominaciõ de cubo. Diremos por tanto q .4. co. por .5. ce. hazen .20. cu. ... si multiplicamos .4. cu. por .8. ce.ce. diremos assi, la denominacion del cubo es .3. y la denominaciõ del censo de censo es .4. q̃ sũmadas hazẽ .7. q̃ sera la denominaciõ dela dignidad engẽdrada, y por que .4. por .8. hazen .32. diremos por tanto, que .4. cu. multiplicados por .8. ce.ce. hazen .32. dignidades, que tienen .7. por denominacion, a que llaman relatos segundos."

Nuñez' division¹ of $12x^3+18x^2+27x+17$ by $4x+3$, yielding the quotient $3x^2+2\frac{1}{4}x+5\frac{1}{6}+\frac{1\frac{1}{6}}{4x+3}$, is as follows:

$$\begin{array}{r}
 \text{"Partidor .4.co.}\bar{p}.3 \left| \begin{array}{l} 12.\text{cu.}\bar{p}.18.\text{ce.}\bar{p}.27.\text{co.}\bar{p}.17. \\ 12.\text{cu.}\bar{p}. \quad 9.\text{ce.} \end{array} \right. \\
 \hline
 \begin{array}{l} 9.\text{ce.}\bar{p}.27.\text{co.}\bar{p}.17. \\ 9.\text{ce.}\bar{p}. \quad 6.\text{co.}\frac{3}{4}. \end{array} \\
 \hline
 \begin{array}{l} 20.\text{co.}\frac{1}{4}.\bar{p}.17. \\ 20.\text{co.}\frac{1}{4}.\bar{p}.15\frac{3}{6}. \end{array} \\
 \hline
 1\frac{1}{6} \\
 \\
 3.\text{ce.}\bar{p}.2.\text{co.}\frac{1}{4}.\bar{p}.5\frac{1}{6}.\bar{p}.1\frac{1}{6} \\
 \text{par .4.co.}\bar{p}.3.
 \end{array}$$

Observe the " $20.\text{co.}\frac{1}{4}$ " for $20\frac{1}{4}x$, the symbol for the unknown appearing between the integer and the fraction.

Cardan's solution of $x^3+3x=36$ is $\sqrt[3]{\sqrt{325+18}}-\sqrt[3]{\sqrt{325-18}}$, and is written by Nuñez as follows:

$$R.V.\text{cu.}R.325.\bar{p}.18.\tilde{m}.R.V.\text{cu.}R.325.\tilde{m}.18.$$

As in many other writers the V signifies *universal* and denotes, not the cube root of $\sqrt{325}$ alone, but of the binomial $\sqrt{325+18}$; in other words, the V takes the place of a parenthesis.

¹ See H. Bosmans, "Sur le 'Libro de algebra' de Pedro Nuñez," *Bibliotheca mathematica*, Vol. VIII (3d ser., 1908), p. 160-62; see also Tropicke, *op. cit.* (2d ed.), Vol. III, p. 136, 137.

ENGLISH: ROBERT RECORDE
(1543[?], 1557)

167. Robert Recorde's arithmetic, the *Ground of Artes*, appeared in many editions. We indicate Recorde's singular notation for proportion:¹

$$\begin{array}{l} \begin{array}{c} 3 \\ 8 \end{array} \text{Z} \begin{array}{c} 16s. \\ 42s. \end{array} \quad (\text{direct}) \quad 3:8 = 16s.:42s. \quad 8d. \\ \begin{array}{c} \frac{3}{4} \\ \frac{5}{12} \end{array} \text{Z} \begin{array}{c} \frac{7}{13} \\ \end{array} \quad (\text{reverse}) \quad \frac{5}{12}:\frac{3}{4} = \frac{7}{13}:x \end{array}$$

There is nothing in Recorde's notation to distinguish between the "rule of proportion direct" and the "rule of porportion reverse." The difference appears in the interpretation. In the foregoing "direct" proportion, you multiply 8 and 16, and divide the product by 3. In the "reverse" proportion, the processes of multiplication and division are interchanged. In the former case we have $8 \times 16 \div 3 = x$, in the second case we have $\frac{3}{4} \times \frac{7}{13} \div \frac{5}{12} = x$. In both cases the large strokes in Z serve as guides to the proper sequence of the numbers.

168. In Recorde's algebra, *The Whetstone of Witte* (London, 1557), the most original and historically important is the sign of equality (=), shown in Figure 71. Notice also the plus (+) and minus (-) signs which make here their first appearance in an English book.

In the designation of powers Recorde uses the symbols of Stifel and gives a table of powers occupying a page and ending with the eightieth power. The seventh power is denoted by $b \int 3$; for the eleventh, thirteenth, seventeenth powers, he writes in place of the letter b the letters c , d , E , respectively. The eightieth power is denoted by $3333 \int 3$, showing that the Hindu multiplicative method of combining the symbols was followed.

Figure 72 shows addition of fractions. The fractions to be added are separated by the word "to." Horizontal lines are drawn above and below the two fractions; above the upper line is written the new numerator and below the lower line is written the new denominator. In "Another Example of Addition," there are added the fractions $\frac{5x^6+3x^5}{6x^9}$ and $\frac{20x^3-6x^5}{6x^9}$.

¹ *Op. cit.* (London, 1646), p. 175, 315. There was an edition in 1543 which was probably the first.

Square root Recorde indicates by $\sqrt{\quad}$, or $\sqrt[3]{\quad}$, cube root by $\sqrt[4]{\quad}$, or $\sqrt[5]{\quad}$. Following Rudolff, he indicates the fourth root by

The Arte

as their woordes doe extende) to diffinate it onely into two partes. Whereof the firste is, when one number is equalle vnto one other. And the seconde is, when one number is compared as equalle vnto, 2, other numbers.

Alwaies willng you to remeber, that you reduce your numbers, to their leaste denominations, and smalleste formes, befoze you procede any farther.

And again, if your equation be soche, that the greatestte denomination Cosike, be ioined to any parte of a compounde number, you shall tourne it so, that the number of the greatestte signe alone, maie stande as equalle to the reste.

And this is all that needeth to be taughte, concerning this woorde.

Howbeit, for easie alteration of equations. I will propounde a fewe crâples, bicause the extraction of their rootes, maie the more aptly bee wroughte. And to auoide the tedious repetition of these wordes: is equalle to: I will sette as I doe often in woorde vse, a paire of paralleles, or Gemowe lines of one lengthe, thus: =====, bicause noe. 2. thynges, can be moare equalle. And now marke these numbers.

1. $14.ze. - | - 15.9. = = = = 71.9.$
2. $20.ze. - - - - 18.9. = = = = 102.9.$
3. $26.8. - | - 10ze = = 9.8. - | - 10ze - | - 213.9.$
4. $19.ze - | - 192.9. = = = 108. - | - 1089 - 19ze$
5. $18.ze - | - 24.9. = = = 8.8. - | - 2.ze.$
6. $348. - - - 12ze = = 40ze - | - 4809 - 9.8.$
1. In the firste there appeareth. 2. numbers, that is
14.ze.

FIG. 71.—From Robert Recorde's *Whetstone of Wille* (1557)

$\sqrt{\quad}$, but Recorde writes it also $\sqrt[3]{\quad}$. Instructive is the dialogue on these signs, carried on between master and scholar:

sented thrise. And \mathcal{W} . standeth for $\sqrt{\mathcal{W}}$. that is .2. figures of *Square* multiplication: and is not expressed with .4. minomes. For so should it seme to expresse moare then .2. *Square* multiplications. But voluntarie signes, it is inoughe to knowe that this thei doe signifie.

Examples of Cubike rootes.

FIG. 73.—Radicals in Recorde's *Whelstone of Wille* (1557)

And if any manne can diuise other, moare easie or apter in use, that maie well be received."

Figure 73 shows the multiplication of radicals. The first two exercises are $\sqrt[3]{91} \times \sqrt[3]{12} = \sqrt[3]{1,092}$, $\sqrt[3]{7\frac{1}{4}} \times \sqrt[3]{\frac{1}{2}} = \sqrt[3]{5\frac{1}{2}}$. Under fourth roots one finds $\sqrt[4]{15} \times \sqrt[4]{7} = \sqrt[4]{105}$.

ENGLISH: JOHN DEE

(1570)

169. John Dee wrote a Preface to Henry Billingsley's edition of *Euclid* (London, 1570). This Preface is a discussion of the mathematical sciences. The radical symbols shown in Figure 74 are those of Stifel. German influences predominated.

This, a diuerſe *Arithmetike* from the other, Practiſe bryngeth in, here, diuerſe compounding of Numbers: as ſome tyme, two, three, foure (or more) *Radicall* nũbers, diuerſly knit, by ſignes, of More & Leſſe: as thus $\sqrt{8} \cdot 12 + \sqrt{c} 15$. Or thus $\sqrt{8} \cdot 8 \cdot 19 + \sqrt{c} 12 - \sqrt{8} \cdot 2$. &c. And ſome tyme with whole numbers, or fractions of whole Number, amõg them: as $20 + \sqrt{8} \cdot 24 \cdot \sqrt{c} 16 + 33 - \sqrt{8} \cdot 10 \cdot \sqrt{8} \cdot 44 + 12 \div + \sqrt{c} 9$. And ſo infinitely, may hap the varietic. After this: Both the one and the other.

FIG. 74.—Radicals, John Dee's Preface to Billingsley's edition of *Euclid* (1570).

In Figure 75 Dee explains that if $a:b=c:d$, then also $a:a-b=c:c-d$. He illustrates this numerically by taking $9:6=12:8$. Notice Dee's use of the word "proportion" in the sense of "ratio." Attention is drawn to the mode of writing the two proportions $9.6:12.8$ and $9.3:12.4$, near the margin. Except for the use of a single colon (:),

conuerſion of proportion, and of ſome euerſion of proportion. Likewyſe in numbers, as 9. to 6, ſo 12. to 8. eyther proportion is ſeſquialtera: the exceſſe of 9. the antecedent of the firſt proportion aboue 9 . 6 : 12 . 8 6. the conſequent of the ſame is 3: the exceſſe of 12. the antecedent of the ſecond proportion aboue 8. the conſequent of the ſame, is 4: now cõpare the antecedent of the firſt proportion 9. as antecedent to 3. the exceſſe thereof aboue 6. the conſequent, as to his conſequent, likewise compare 12. the antecedent of the ſecond proportion as antecedent to 4. the exceſſe thereof aboue 8. the conſequent, as to his conſequent: ſo ſhall your numbers be in this order by conuerſion of proportion: as 9. to 3: ſo 12. to 4: for either proportion is triple.

FIG. 75.—Proportion in John Dee's Preface to Billingsley's edition of *Euclid* (1570).

in place of the double colon (: :), this is exactly the notation later used by Oughtred in his *Clavis mathematicae*. It is possible that Oughtred took the symbols from Dee. Dee's Preface also indicates the origin of these symbols. They are simply the rhetorical marks used in the text. See more particularly the second to the last line, "as 9. to 3: so 12. to 4:"

ENGLISH: LEONARD AND THOMAS DIGGES
(1579)

170. The *Stratoticos*¹ was brought out by Thomas Digges, the son of Leonard Digges. It seems that the original draft of the book was the work of Leonard; the enlargement of the manuscript and its preparation for print were due to Thomas.

The notation employed for powers is indicated by the following quotations (p. 33):

"In this Arte of Numbers Cossical, wae proceede from the Roote by Multiplication, to create all Squares, Cubes, Zenzizenzike, and Sur Solides, wyth all other that in this Science are used, the whyche by Example maye best bee explained.

1	2	3	4	5	6	7	8	9	10	11	12
Roo.	Sq.	Cu.	SqS.	S ∫ o.	SqC.	B ∫ S.	SSSq.	CC.	S ∫ S.	C ∫ S.	SSC.
2	4	8	16	32	64	128	256	512	1024	2048	4096

Again (p. 32):

"... Of these [Roote, Square, Cube] are all the rest composed. For the Square being four, againe squared, maketh his *Squared square* 16, with his Character ouer him. The nexte being not made by the Square or Cubike, Multiplication of any of the former, can not take his name from *Square* or *Cube*, and is therefore called a *Surd solide*, and is onely created by Multiplicatiō of 2 the Roote, in 16 the SqS. making 32 with his cōuenient Character ouer him & for distinctiō is tearmed $\frac{y}{y}$ first *Surd solide* . . . the nexte being 128, is not made of square or Cubique Multiplication of any, but only by the Multiplication of the Squared Cube in his Roote, and therefore is tearmed the *B.S.solide*, or seconde S. solide. . . .

"This I have rather added for custome sake, bycause in all parts of the world these *Characters* and names of *Sq.* and *Cu.* etc. are used, but bycause I find another kinde of *Character* by my Father deuised, farre more readie in *Multiplications*, *Diuisions*, and other *Cossical* operations, I will not doubt, hauing Reason on my side, to dissent from common custome in this poynt, and vse these *Characters* ensuing: [What follows is on page 35 and is reproduced here in Fig. 76]."

¹ *An Arithmeticall Militare Treatise, named Stratoticos: compendiously teaching the Science of Nūbers, as well in Fractions as Integers, and so much of the Rules and Acquations Algebraicall and Arte of Numbers Cossicall, as are requisite for the Profession of a Soldiour. Together with the Moderne Militare Discipline, Offices, Lawes and Duties in euery wel gouerned Campe and Armie to be observed: Long since attempted by Leonard Digges Gentleman, Augmented, digested, and lately finished, by Thomas Digges, his Sonne* . . . (At London, 1579).

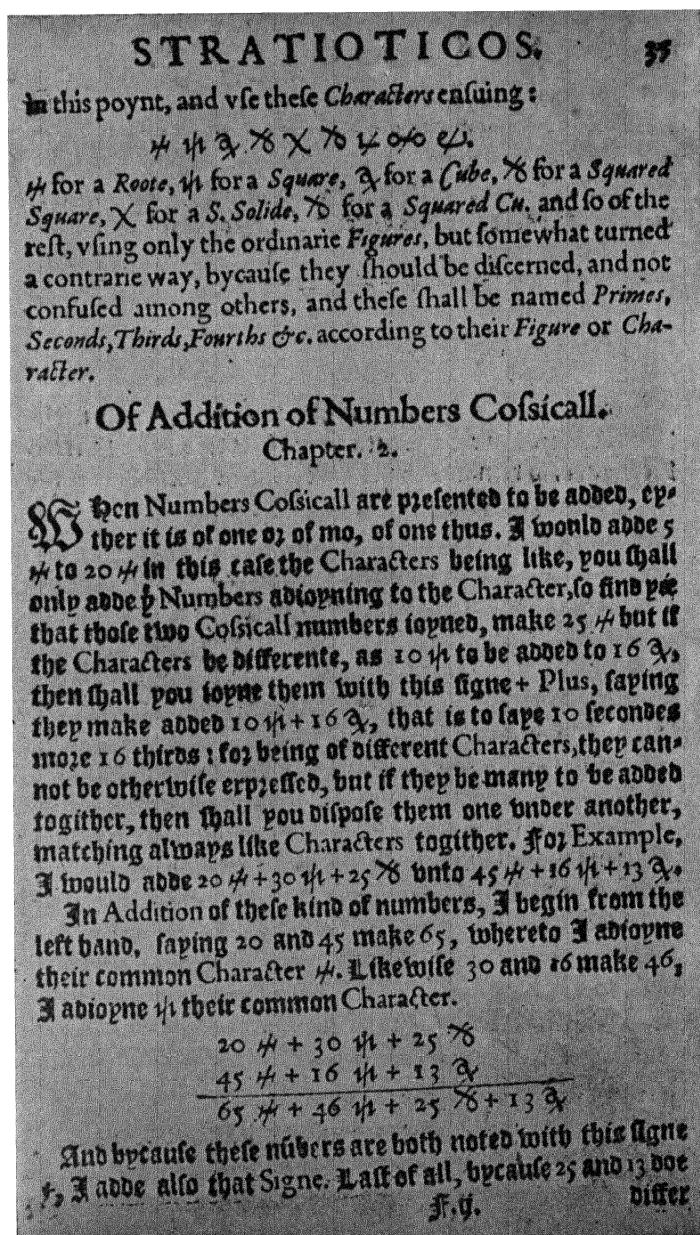

FIG. 76.—Leonard and Thomas Digges, *Stratioticos* (1579), p. 35, showing the unknown and its powers to x^9 .

As stated by the authors, the symbols are simply the numerals somewhat disfigured and crossed out by an extra stroke, to prevent confusion with the ordinary figures. The example at the bottom of page 35 is the addition of $20x+30x^2+25x^3$ and $45x+16x^2+13x^3$. It is noteworthy that in 1610 Cataldi in Italy devised a similar scheme for representing the powers of an unknown (§ 340).

The treatment of equations is shown on page 46, which is reproduced in Figure 77. Observe the symbol for zero in lines 4 and 7; this form is used only when the zero stands by itself.

A little later, on page 51, the authors, without explanation, begin to use a sign of equality. Previously the state of equality had been expressed in words, "equall to," "are." The sign of equality looks as if it were made up of two letters *C* in these positions $\mathcal{C}\mathcal{C}$ and crossed by two horizontal lines. See Figure 78.

This sign of equality is more elaborate than that previously devised by Robert Recorde. The Digges sign requires four strokes of the pen; the Recorde sign demands only two, yet is perfectly clear. The Digges symbol appears again on five or more later pages of the *Stratoticos*. Perhaps the sign is the astronomical symbol for *Pisces* ("the Fishes"), with an extra horizontal line. The top equation on page 51 is $x^2=6x+27$.

ENGLISH: THOMAS MASTERSON
(1592)

171. The domination of German symbols over English authors of the sixteenth century is shown further by the *Arithmeticke* of Thomas Masterson (London, 1592). Stifel's symbols for powers are used. We reproduce (in Fig. 79) a page showing the symbols for radicals.

FRENCH: JACQUES PELETIER
(1554)

172. Jacques Peletier du Mans resided in Paris, Bordeaux, Beziers, Lyon, and Rome. He died in Paris. His algebra, *De occulta Parte Numerorum, Quam Algebram vocant, Libri duo* (Paris, 1554, and several other editions),¹ shows in the symbolism used both German and Italian influences: German in the designation of powers and roots, done in the manner of Stifel; Italian in the use of *p.* and *m.* for "plus" and "minus."

¹ All our information is drawn from H. Bosmans, "L'algèbre de Jacques Peletier du Mans," *Extrait de la revue des questions scientifiques* (Bruxelles: January, 1907), p. 1-61.

46

STRATIOTICOS.

Sometimes it shall be requisite to take away some number from either part of the Equation, as if I haue $6x$ Equall to $12x - 24$, deducting from either part of the Equation $6x$, there resteth x Equall to $6x - 24$, and therefore of necessity $6x$ is equall to 24 , for this Rule is general. What if you bring an Equation (by suche Deduction) to a $+$ on the one part, there must be some member in the other connered with the Signe Minus, the which is alwayes Equall to all the rest of that part of the Equation.

Sometimes Reduction is made by adding together all suche parcels, as on the one side of the Equation haue equal Characters, as if $1x$ be Equall to $3x + 16x - 1x - 10x$. Here by adding $+16x$ to $-10x$, there resulteth $+6x$, so that I say $1x$ is equall to $3x + 6x - 1x$, and the same diuided by $1x$ maketh $1x$ Equall to $3x + 6 - 1x$.

Reduction of Fragments which shall
happen in Equations to
Integers.

Another kinde of Reduction there is of Fragmentes to whole numbers, which commeth in vse when an Equation is founde betwene Fractions on the one or both parts, as if $\frac{4x+2}{2x}$ be Equall unto $\frac{2x-2x}{1x}$, by crosse

multiplication of the Denominator of the one in the Numerator of the other, I finde these two numbers produced $4x+2x$, and $6x-4x$. Betwene these, the like Equation remaineth, and the same first reduced by transporting of Signes, maketh $4x$ Equall to $6x - 2x - 4x$. Then by Addition of $6x$ to $-2x$, there resulteth $4x - 4x$, equall to $4x$. Again, diuiding either part of the Equation by $4x$, there resulteth $1x$ Equall to $1x - 1x$. And last of all, deducting $1x$ from both partes of the Equation, I finde x equall to $1x - 2x$, and therefore of necessity as was declared.

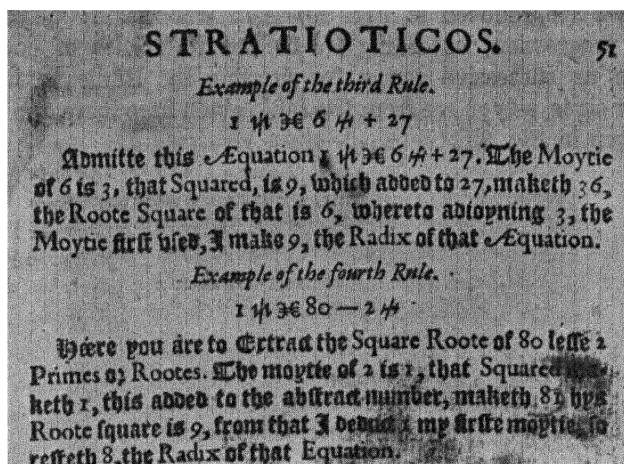

FIG. 78.—Sign of equality in Digges, *Stratiotics* (1579). This page exhibits also the solution of quadratic equations.

ARITHMETICKE LIB. III.

43

Examples.

FIG. 79.—Thomas Masterson, *Arithmeticke* (1592), part of p. 45

Page 8 (reproduced in Fig. 80) is in translation: "[The arithmetical progression, according to the natural order of counting,] furnishes us successive terms for showing the Radicand numbers and their signs, as you see from the table given here [here appears the table given in Fig. 80].

8 PREMIER LIVRE

nous fournit de termes consecutiz, pour exposer les nombres Radicaux e leurs Signes: comme vous voyez par la Table ici mise.

0,	1,	2,	3,	4	5,	6,	7,	8,	9,	10,
1,	B,	3,	4,	55,	β,	55,	bβ,	555,	555,	5β,
1,	2,	4,	8,	16,	32,	64,	128,	256,	512,	1024,
11,	12,	13,	14,	15,	16,					
cβ,	555,	dβ,	5bβ,	55,	5555,					
2048,	4096,	8192,	16384,	32768,	65536,					

Au premier rang, est la Progression Arithmetique, selon la consecution naturelle des Nombres: Et l'vnite, qui est au dessus de B, se nommeta l'exposant de ce signe B: et 2 qui est au dessus de 3, sera l'exposant de ce signe 3: Et 3, l'exposant de 4: de 55, e ainsi par ordre.

Au second rang, sont les Caracteres des nombres Radicaux qui appartiennent a l'Algebre, portans leur denomination. Sauer et B, Racine: 3, Cansse: 4, Cube: 55, Canssante &c.

Au tiers rang, est la Progression Geometrique Double: La ou vous voyez 2 pour Racine, estre souz ce signe B: 4, nombre Cansique, souz son signe de 3: 8, Cubique, touz son signe 4, &c. Telement que le dernier termine, qui

FIG. 80.—Designation of powers in J. Peletier's *Algebra* (1554)

"In the first line is the arithmetical progression, according to the natural order of the numbers; and the one which is above the B numbers the exponent of this sign B; the 2 which is above the 3 is the exponent of this sign 3; and 3 is the exponent of c, 4 of β, and so on.

"In the second line are the characters of the Radicand numbers

which pertain to algebra, marking their denomination." Then are explained the names of the symbols, as given in French, viz., *R* racine, *ç* çanse, *c* cube, etc.

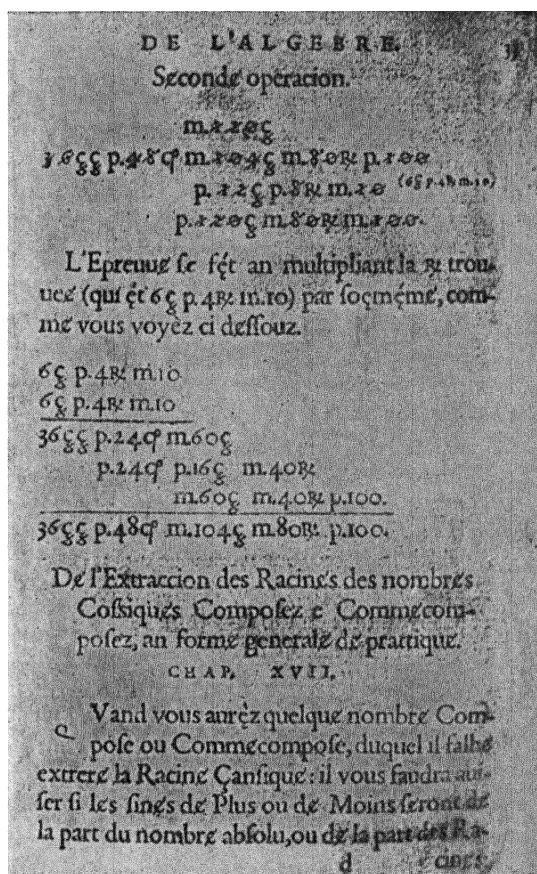

FIG. 81.—Algebraic operations in Peletier's *Algebra* (1554)

Page 33 (shown in Fig. 81) begins with the extraction of a square root and a "proof" of the correctness of the work. The root extraction is, in modern symbols:

$$\begin{aligned}
 & -120x^2 \\
 36x^4 + 48x^3 - 104x^2 - 80x + 100 \\
 & + 12x^2 + 8x - 10(6x^2 + 4x - 10) \\
 & + 120x^2 + 80x - 100.
 \end{aligned}$$

The "proof" is thus:

$$\begin{array}{r}
 6x^2 + 4x - 10 \\
 6x^2 + 4x - 10 \\
 \hline
 36x^4 + 24x^3 - 60x^2 \\
 + 24x^3 + 16x^2 - 40x \\
 - 60x^2 - 40x + 100 \\
 \hline
 36x^4 + 48x^3 - 104x^2 - 80x + 100
 \end{array}$$

Further on in this book Peletier gives:

$$\sqrt[3]{15} \text{ p. } \sqrt[3]{8}, \text{ signifying } \sqrt[3]{15} + \sqrt[3]{8}.$$

$$\sqrt[3]{15} \cdot 15 \text{ p. } \sqrt[3]{8}, \text{ signifying } \sqrt[3]{15 + \sqrt[3]{8}}.$$

FRENCH: JEAN BUTEON

(1559)

173. Deeply influenced by geometrical considerations was Jean Buteon,¹ in his *Logistica quae et Arithmetica vulgo dicitur* (Lugduni, 1559). In the part of the book on algebra he rejects the words *res*, *census*, etc., and introduces in their place the Latin words for "line," "square," "cube," using the symbols ρ , \diamond , \square . He employs also P and M , both as signs of operation and of quality. Calling the sides of an equation *continens* and *contentum*, respectively, he writes between them the sign [as long as the equation is not reduced to the simplest form and the *contentum*, therefore, not in its final form. Later the *contentum* is inclosed in the completed rectangle []. Thus Buteon writes $3\rho \text{ } M \text{ } 7 \text{ } [\text{ } 8$ and then draws the inferences, $3\rho \text{ } [15]$, $1\rho \text{ } [5]$. Again he writes $\frac{1}{4} \diamond [100$, hence $1\diamond [400]$, $1\rho [20]$. In modern symbols: $3x-7=8$, $3x=15$, $x=5$; $\frac{1}{4}x^2=100$, $x^2=400$, $x=20$. Another example: $\frac{1}{8} \square P \text{ } 2 \text{ } [218$, $\frac{1}{8} \square [216$, $1 \square [1728]$, $1\rho [12]$; in modern form $\frac{1}{8}x^3+2=218$, $\frac{1}{8}x^3=216$, $x^3=1,728$, $x=12$.

When more than one unknown quantity arises, they are represented by the capitals A , B , C . Buteon gives examples involving only positive terms and then omits the P . In finding three numbers subject to the conditions $x+\frac{1}{2}y+\frac{1}{3}z=17$, $y+\frac{1}{3}x+\frac{1}{8}z=17$, $z+\frac{1}{4}x+\frac{1}{4}y=17$, he writes:

$$1A, \frac{1}{2}B, \frac{1}{3}C [17$$

$$1B, \frac{1}{3}A, \frac{1}{8}C [17$$

$$1C, \frac{1}{4}A, \frac{1}{4}B [17$$

¹ Our information is drawn from G. Werthheim's article on Buteon, *Bibliotheca mathematica*, Vol. II (3d ser., 1901), p. 213-19.

and derives from them the next equations in the solution:

$$\begin{aligned} 2A \cdot 1B \cdot 1C & [34 \\ 1A \cdot 3B \cdot 1C & [51 \\ 1A \cdot 1B \cdot 4C & [68, \text{etc.} \end{aligned}$$

In Figure 82 the equations are as follows:

$$3A + 12B + 3C = 96$$

$$3A + 1B + 1C = 42$$

$$11B + 2C = 54$$

$$3A + 3B + 15C = 120$$

$$3A + 1B + 1C = 42$$

$$2B + 14C = 78$$

$$22B + 154C = 858$$

$$22B + 4C = 108$$

$$150C = 750$$

FRENCH: GUILLAUME GOSSELIN

(1577)

174. A brief but very good elementary exposition of algebra was given by G. Gosselin in his *De arte magna*, published in Paris in 1577. Although the plus (+) and minus (−) signs must have been more or less familiar to Frenchmen through the *Algebra* of Scheubel, published in Paris in 1551 and 1552, nevertheless Gosselin does not use them. Like Peletier, Gosselin follows the Italians on this point, only Gosselin uses the capital letters *P* and *M* for “plus” and “minus,” instead of the usual and more convenient small letters.¹ He defines his notation for powers by the following statement (chap. vi, fol. v):

$L \cdot 2 \cdot Q \cdot 4 \cdot C \cdot 8 \cdot QQ \cdot 16 \cdot RP \cdot 32 \cdot QC \cdot 64 \cdot RS \cdot 128 \cdot CC \cdot 512$.

Here *RP* and *RS* signify, respectively, *relatum primum* and *relatum secundum*.

Accordingly,

“12*L* *M* 1*Q* *P* 48 aequalia 144 *M* 24*L* *P* 2*Q*”

means

$$12x - x^2 + 48 = 144 - 24x + 2x^2.$$

¹ Our information is drawn mainly from H. Bosmans' article on Gosselin, *Bibliotheca mathematica*, Vol. VII (1906-7), p. 44-66.

The translation of Figure 83 is as follows:

" . . . Thus I multiply $4x-6x^2+7$ by $3x^2$ and there results $12x^3-18x^4+21x^2$ which I write below the straight line; then I multi-

On the Division of Integers, chapter viii

Four Rules

- + divided in + the quotient is +
- divided in - the quotient is +
- divided in + the quotient is -
- + divided in - the quotient is - "

175. Proceeding to radicals we quote (fol. 47B): "Est autem laterum duplex genus simplicium et compositorum. Simplicia sunt *L9*, *LC8*, *LL16*, etc. Composita vero ut *LV24 P L29*, *LV6 P L8*." In translation: "There are moreover two kinds of radicals, simple and composite. The simple are like $\sqrt{9}$, $\sqrt[3]{8}$, $\sqrt[4]{16}$, etc. The composite are like $\sqrt{24+\sqrt{29}}$, $\sqrt{6+\sqrt[3]{8}}$." First to be noticed is the difference between *L9* and *9L*. They mean, respectively, $\sqrt{9}$ and $9x$. We have encountered somewhat similar conventions in Pacioli, with whom *R* meant a power when used in the form, say, "*R* . 5^a" (i.e., x^4), while *R* meant a root when followed by a number, as in *R* .200. (i.e., $\sqrt{200}$) (see § 135). Somewhat later the same principle of relative position occurs in Albert Girard, but with a different symbol, the circle. Gosselin's *LV* meant of course *latus universale*. Other examples of his notation of radicals are *LVL10 P L5*, for $\sqrt{\sqrt{10}+\sqrt{5}}$, and *LVCL5 P LC10* for $\sqrt[3]{\sqrt{5}+\sqrt[3]{10}}$.

In the solution of simultaneous equations involving only positive terms Gosselin uses as the unknowns the capital letters *A*, *B*, *C*, . . . (similar to the notation of Stifel and Buteon), and omits the sign *P* for "plus"; he does this in five problems involving positive terms, following here an idea of Buteo. In the problem 5, taken from Buteo, Gosselin finds four numbers, of which the first, together with half of the remaining, gives 17; the second with the third of the remaining gives 12; and the third with a fourth of the remaining gives 13; and

the fourth with a sixth of the remaining gives 13. Gosselin lets A, B, C, D be the four numbers and then writes:

$$\begin{array}{ll} \text{Modern Notation} \\ \text{" } 1A\frac{1}{2}B\frac{1}{3}C\frac{1}{3}D \text{ aequalia } 17, & x + \frac{1}{2}y + \frac{1}{3}z + \frac{1}{3}w = 17, \\ 1B\frac{1}{3}A\frac{1}{3}C\frac{1}{3}D \text{ aequalia } 12, \text{ etc. " } & y + \frac{1}{3}x + \frac{1}{3}z + \frac{1}{3}w = 12. \end{array}$$

He is able to effect the solution without introducing negative terms.

In another place Gosselin follows Italian and German writers in representing a second unknown quantity by q , the contraction of *quantitas*. He writes (fols. 84B, 85A) " $1L P 2q M 20$ aequalia sunt $1L P 30$ " (i.e., $1x + 2y - 20 = 1x + 30$) and obtains " $2q$ aequales 50, fit $1q 25$ " (i.e., $2y = 50, y = 25$).

FRENCH: FRANCIS VIETA
(1591 and Later)

176. Sometimes, Vieta's notation as it appears in his early publications is somewhat different from that in his collected works, edited by Fr. van Schooten in 1646. For example, our modern $\frac{3BD^2 - 3BA^2}{4}$ is printed in Vieta's *Zeteticorum libri v* (Tours, 1593) as

$$\frac{\text{" } B \text{ in } D \text{ quadratum } 3 - B \text{ in } A \text{ quadratum } 3 \text{ "}}{4},$$

while in 1646 it is reprinted¹ in the form

$$\frac{\text{" } B \text{ in } Dq \ 3 - B \text{ in } Aq \ 3 \text{ "}}{4}.$$

Further differences in notation are pointed out by J. Tropfke:²

$$\begin{array}{l} \text{Zeteticorum libri v (1593)} \\ \text{Fol. 3B: } \quad \frac{B \text{ in } A}{D} + \left\{ \frac{B \text{ in } A}{-B \text{ in } H} \right\} \frac{F}{F} \text{ aequabuntur } B. \\ \text{Modern: } \quad \frac{Bx}{D} + \frac{Bx - B \cdot H}{F} = B. \end{array}$$

$$\text{Lib. II, 22:} \quad "l \frac{25}{3} - l \frac{5}{3}."$$

¹ *Francisci Vietae Opera mathematica* (ed. Fr. à Schooten; Lvgdvni Batavorvm, 1646), p. 60. This difference in notation has been pointed out by H. Bosmans, in an article on Oughtred, in *Extrait des annales de la société scientifique de Bruxelles*, Vol. XXXV, fasc. 1 (2d part), p. 22.

² *Op. cit.*, Vol. III (2d ed., 1922), p. 139.

Lib. IV, 10: “ B in $\left\{ \begin{array}{l} D \text{ quadratum} \\ + B \text{ in } D \end{array} \right\} .”$

Modern: $B(D^2 + BD)$.

Lib. IV, 20: “ D in $\left\{ \begin{array}{l} B \text{ cubum } 2 \\ - D \text{ cubo} \end{array} \right\} .”$

Modern: $D(2B^3 - D^3)$.

Van Schooten edition of Vieta (1646)

P. 46: “ $\frac{B \text{ in } A}{D} + \frac{B \text{ in } A - B \text{ in } H}{F}$ aequabitur B .”

P. 56: “ $\sqrt{\frac{25}{3}} - \sqrt{\frac{5}{3}} .”$

P. 70: “ B in $\overline{D \text{ quad.} + B \text{ in } D} .”$

P. 74: “ \overline{D} in $\overline{B \text{ cubum } 2 - D \text{ cubo}} .”$

Figure 84 exhibits defective typographical work. As in Stifel's *Arithmetica integra*, so here, the fractional line is drawn too short. In the translation of this passage we put the sign of multiplication (\times) in place of the word *in*: “. . . . Because what multiplication brings about above, the same is undone by division, as $\frac{B \times A}{B}$, i.e., A ; and $\frac{B \times A^2}{B}$ is A^2 .

Thus in additions, required, to $\frac{A^2}{B}$ to add Z . The sum is $\frac{A^2 + Z \times B}{B}$; or required, to $\frac{A^2}{B}$ to add $\frac{Z^2}{G}$. The sum is $\frac{G \times A^2 + B \times Z^2}{B \times G}$.

In subtraction, required, from $\frac{A^2}{B}$ to subtract Z . The remainder is $\frac{A^2 - Z \times B}{B}$. Or required, from $\frac{A^2}{B}$ to subtract $\frac{Z^2}{G}$. The remainder is $\frac{A^2 \times G - Z^2 \times B}{B \times G}$.”

Observe that Vieta uses the signs plus (+) and minus (−), which had appeared at Paris in the *Algebra* of Scheubel (1551). Outstanding in the foregoing illustrations from Vieta is the appearance of capital letters as the representatives of general magnitudes. Vieta was the first to do this systematically. Sometimes, Regiomontanus, Rudolff, Adam Riese, and Stifel in Germany, and Cardan in Italy, used letters at an earlier date, but Vieta extended this idea and first made it an

essential part of algebra. Vieta's words,¹ as found in his *Isagoge*, are: "That this work may be aided by a certain artifice, given magnitudes are to be distinguished from the uncertain required ones by a symbolism, uniform and always readily seen, as is possible by designating the required quantities by letter *A* or by other vowel letters *A, I, O, V, Y*, and the given ones by the letters *B, G, D* or by other consonants."²

Vieta's use of letters representing known magnitudes as coefficients of letters representing unknown magnitudes is altogether new. In discussing Vieta's designation of unknown quantities by vowels,

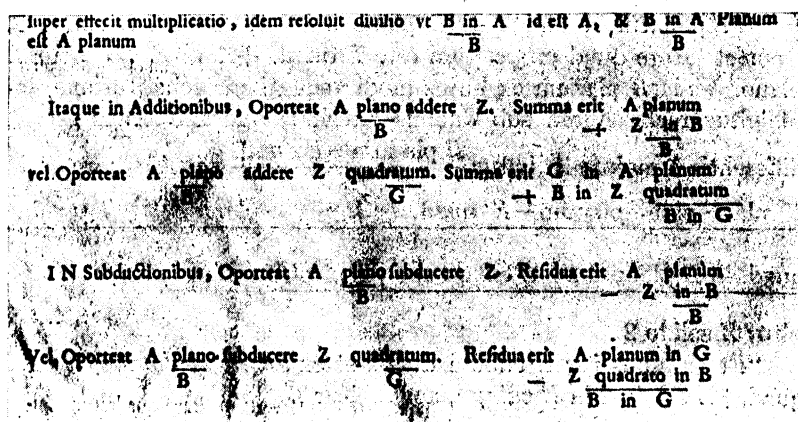

FIG. 84.—From Vieta's *In artem analyticam Isagoge* (1591). (I am indebted to Professor H. Bosmans for this photograph.)

C. Henry remarks: "Thus in a century which numbers fewer Orientalists of eminence than the century of Vieta, it may be difficult not to regard this choice as an indication of a renaissance of Semitic languages; every one knows that in Hebrew and in Arabic only the consonants are given and that the vowels must be recovered from them."³

177. Vieta uses = for the expression of arithmetical difference. He says: "However when it is not stated which magnitude is the greater and which is the less, yet the subtraction must be carried out,

¹ Vieta, *Opera mathematica* (1646), p. 8.

² "Quod opus, ut arte aliqua juvetur, symbolo constanti et perpetuo ac bene conspicuo date magnitudines ab incertis quaesitiis distinguantur, ut pote magnitudines quaesitiis elemento A aliave litera vocali, *E, I, O, V, Y* datas elementis *B, G, D*, aliisve consonis designando."

³ "Sur l'origine de quelques notations mathématiques," *Revue archéologique*, Vol. XXXVIII (N.S., 1879), p. 8.

the sign of difference is $=$, i.e., an uncertain minus. Thus, given A^2 and B^2 , the difference is $A^2=B^2$, or $B^2=A^2$.¹

We illustrate Vieta's mode of writing equations in his *Isagoge*: " B in A quadratum plus D plano in A aequari Z solido," i.e., $BA^2 + D^2A = Z^3$, where A is the unknown quantity and the consonants are the known magnitudes. In Vieta's *Ad Logisticen speciosam notae priores* one finds: " A cubus, $+A$ quadrato in B ter, $+A$ in B quadratum ter, $+B$ cubo," for $A^3 + 3A^2B + 3AB^2 + B^3$.²

We copy from Vieta's *De emendatione aequationum tractatus secundus* (1615),³ as printed in 1646, the solution of the cubic $x^3 + 3B^2x = 2Z^3$:

"Proponatur A cubus $+ B$ plano 3 in A , aequari Z solido 2. Oportet facere quod propositum est. E quad. $+A$ in E , aequetur B plano. Vnde B planum ex hujus modi aequationis constitutione, intelligitur rectangulum sub duobus lateribus quorum minus est E , differentia à majore A . igitur $\frac{B \text{ planum} - E \text{ quad.}}{E}$ erit A . Quare $\frac{B \text{ plano-plano-plano} - E \text{ quad. in } B \text{ plano-plano} 3 + E \text{ quad.}}{E \text{ cubo}}$ quad. in B planum 3 $- E$ cubo-cubo $+ \frac{B \text{ pl. pl. 3.} - B \text{ pl. in Eq. 3}}{E}$ aequabitur Z solido 2.

"Et omnibus per E cubum ductis et ex arte concinnatis, E cubi quad. $+ Z$ solido 2 in E cubum, aequabitur B plani-cubo.⁴

"Quae aequatio est quadrati affirmate affecti, radicem habentis solidam. Facta itaque reductio est quae imperabatur.

"*Confectarium*: Itaque si A cubus $+ B$ plano 3 in A , aequetur Z solido 2, & \sqrt{B} plano-plano-plani $+ Z$ solido-solido $- Z$ solido, aequetur D cubo. Ergo $\frac{B \text{ planum} - D \text{ quad.}}{D}$, sit A de qua quaeritur."

Translation: "Given $x^3 + 3B^2x = 2Z^3$. To solve this, let $y^2 + yx = B^2$. Since B^2 from the constitution of such an equation is understood to be a rectangle of which the less of the two sides is y , and the difference between it and the larger side is x . Therefore $\frac{B^2 - y^2}{y} = x$. Whence

$$\frac{B^3 - 3B^4y^2 + 3B^2y^4 - y^6}{y^3} + \frac{3B^4 - 3B^2y^2}{y} = 2Z^3.$$

¹ "Cum autem non proponitur ultra magnitudo sit major vel minor, et tamen subductio facienda est, nota differentiae est $=$ id est, minus incerto: ut propositis A quadrato et B plano, differentia erit A quadratum $= B$ plano, vel B planum $A =$ quadrato" (Vieta, *Opera mathematica* [1646], p. 5).

² *Ibid.*, p. 17.

³ *Ibid.*, p. 149.

⁴ " B plani-cubo" should be " B cubo-cubo," and " E cubi quad." should be " E cubo-cubo."

All terms being multiplied by y^3 , and properly ordered, one obtains $y^6 + 2Z^3y^3 = B^6$. As this equation is quadratic with a positive affected term, it has also a cube root. Thus the required reduction is effected.

"*Conclusion:* If therefore $x^3 + 3B^2x = 2Z^3$, and $\sqrt{B^6 + Z^6 - Z^3} = D^3$, then $\frac{B^2 - D^2}{D}$ is x , as required."

The value of x in $x^3 + 3B^2x = 2Z^3$ is written on page 150 of the 1646 edition thus:

" $\sqrt{C.\sqrt{B \text{ plano-plano-plani} + Z \text{ solido-solido} + Z \text{ solido} -$

$\sqrt{C.\sqrt{B \text{ plano-plano-plani} + Z \text{ solido-solido} - Z \text{ solido} .}}$ "

The combining of vinculum and radical sign shown here indicates the influence of Descartes upon Van Schooten, the editor of Vieta's collected works. As regards Vieta's own notations, it is evident that compactness was not secured by him to the same degree as by earlier writers. For powers he did not adopt either the Italian symbolism of Pacioli, Tartaglia, and Cardan or the German symbolism of Rudolff and Stifel. It must be emphasized that the radical sign, as found in the 1646 edition of his works, is a modification introduced by Van Schooten. Vieta himself rejected the radical sign and used, instead, the letter l (*latus*, "the side of a square") or the word *radix*. The l had been introduced by Ramus (§ 322); in the *Zeteticorum*, etc., of 1593 Vieta wrote $l. 121$ for $\sqrt{121}$. In the 1646 edition (p. 400) one finds $\sqrt{2 + \sqrt{2 + \sqrt{2 + \sqrt{2}}}}$, which is Van Schooten's revision of the text of Vieta; Vieta's own symbolism for this expression was, in 1593,¹

"*Radix binomiae 2*

+ *Radix binomiae* $\left\{ \begin{array}{l} 2 \\ + \text{radix binomiae} \left\{ \begin{array}{l} 2 \\ + \text{radice 2} \end{array} \right. \end{array} \right.$,"

and in 1595,²

"*R. bin. 2 + R. bin. 2 + R. bin. 2 + R. 2. ,*"

a notation employed also by his contemporary Adrian Van Roomen.

178. Vieta distinguished between number and magnitude even in his notation. In numerical equations the unknown number is no longer represented by a vowel; the unknown number and its powers are represented, respectively, by N (*numerus*), Q (*quadratus*), C (*cubus*), and

¹ *Variorum de rebus mathem. Responsorum liber VIII* (Tours, 1593), corollary to Caput XVIII, p. 12v°. This and the next reference are taken from Tropicke, *op. cit.*, Vol. II (1921), p. 152, 153.

² *Ad Problema quod omnibus mathematicis totius orbis construendum proposuit Adrianus Romanus, Francisci Vietae responsum* (Paris, 1595), Bl. A IV°.

combinations of them. Coefficients are now written to the left of the letters to which they belong.

Thus,¹ "Si $65C - 1QQ$, aequetur 1,481,544, fit $1N57$," i.e., if $65x^3 - x^4 = 1,481,544$, then $x = 57$. Again,² the "B3 in A quad." occurring in the regular text is displaced in the accompanying example by "6Q," where $B = 2$.

Figure 85 further illustrates the notation, as printed in 1646.

Vieta died in 1603. The *De emendatione aequationum* was first printed in 1615 under the editorship of Vieta's English friend, Alexander Anderson, who found Vieta's manuscript incomplete and con-

THEOREMA I.

S₁ A cubus + B in A quadr. 3 + D plano in A, æquetur B cubo 2 — D plano in B. A quad. + B in A 2, æquabitur B quad. 2 — D plano.

Quoniam enim A quadr. + B in A 2, æquatur B quadr. 2 — D plano. Duëtis igitur omnibus in A. A cubus + B in A quadr. 2, æquabitur B quad. in A 2 — D plano in A.

Et iisdem duëtis in B. B in A quad. + B quadr. in A 2, æquabitur B cubo 2 — D plano in B. Iungatur ducta æqualia æqualibus. A cubus + B in A quadr. 3 + B quad. in A 2, æquabitur B quad. in A 2 — D plano in A + B cubo 2 — D plano in B.

Et deleta utrinque adfectione B quad. in A 2, & ad æqualitatis ordinationem, translata per antithesin D plani in A adfectione. A cubus + B in A quadr. 3 + D plano in A, æquabitur B cubo 2 — D plano in B. Quod quidem ita se habet.

$1C + 30Q + 44N$, æquatur 1560. Igitur $1Q + 20N$, æquabitur 156. & fit 1N6.

FIG. 85.—From Vieta's *De emendatione aequationum*, in *Opera mathematica* (1646), p. 154.

taining omissions which had to be supplied to make the tract intelligible. The question arises, Is the notation N , Q , C due to Vieta or to Anderson?³ There is no valid evidence against the view that Vieta did use them. These letters were used before Vieta by Xylander in his edition of Diophantus (1575) and in Van Schooten's edition⁴ of the *Ad problema, quod omnibus mathematicis totius orbis construendum proposuit Adrianus Romanus*. It will be noticed that the letter N stands here for x , while in some other writers it is used in the designation of absolute number as in Grammateus (1518), who writes our $12x^3 - 24$ thus: "12 ter. mi. $24N$." After Vieta N appears as a mark for absolute number in the *Sommaire de l'algebre* of Denis Henrion⁵

¹ Vieta, *Opera mathematica* (1646), p. 223.

² *Op. cit.*, p. 130.

³ See Eneström, *Bibliotheca mathematica*, Vol. XIII (1912-13), p. 166, 167.

⁴ Vieta, *Opera mathematica* (1646), p. 306, 307.

⁵ Denis Henrion, *Les quinze livres des elemens d'Euclide* (4th ed.; Paris, 1631), p. 675-788. First edition, Paris, 1615. (Courtesy of Library of University of Michigan.)

which was inserted in his French edition of Euclid. Henrion did not adopt Vieta's literal coefficients in equations and further showed his conservatism in having no sign of equality, in representing the powers of the unknown by R , q , c , qq , β , qc , $b\beta$, qqq , cc , $q\beta$, $c\beta$, qqc , etc., and in using the "scratch method" in division of algebraic polynomials, as found much earlier in Stifel.¹ The one novel feature in Henrion was his regular use of round parentheses to express aggregation.

ITALIAN: BONAVENTURA CAVALIERI
(1647)

179. Cavalieri's *Geometria indivisibilibus* (Bologna, 1635 and 1653) is as rhetorical in its exposition as is the original text of Euclid's *Elements*. No use whatever is made of arithmetical or algebraic signs, not even of $+$ and $-$, or p and m .

An invasion of German algebraic symbolism into Italy had taken place in Clavius' *Algebra*, which was printed at Rome in 1608. That German and French symbolism had gained ground at the time of Cavalieri appears from his *Exercitationes geometriae sex* (1647), from which Figure 86 is taken. Plus signs of fancy shape appear, also Vieta's *in* to indicate "times." The figure shows the expansion of $(a+b)^n$ for $n=2, 3, 4$. Observe that the numerical coefficients are written after the literal factors to which they belong.

ENGLISH: WILLIAM OUGHTRED
(1631, 1632, 1657)

180. William Oughtred placed unusual emphasis upon the use of mathematical symbols. His symbol for multiplication, his notation for proportion, and his sign for difference met with wide adoption in Continental Europe as well as Great Britain. He used as many as one hundred and fifty symbols, many of which were, of course, introduced by earlier writers. The most influential of his books was the *Clavis mathematicae*, the first edition² of which appeared in 1631, later Latin editions of which bear the dates of 1648, 1652, 1667, 1693.

¹ M. Stifel, *Arithmetica integra* (1544), fol. 239A.

² The first edition did not contain *Clavis mathematicae* as the leading words in the title. The exact title of the 1631 edition was: *Arithmeticae in|numeris et speci|ebus institutio|Qvae tm logisticae, tm analyti|cae, atque adeo|totius mathematicae, quasi|clavis|est.*—*Ad nobilissimum spe|ctatissimumque iuvenem Dn. Gvilel|mvm Howard, Ordinis, qui dicitur, Balnei Equitem, honoratissimi Dn. Thomae, Comitis Arundeliae & |Svrviae, Comitis Mareschal|li Angliae, &c. filium.*—*Londoni,|Apud Thomam Harperum,| M. DC. xxxi.*

A second impression of the 1693 or fifth edition appeared in 1698. Two English editions of this book came out in 1647 and 1694.

procedendum i proposuionum veritas appret.

FIG. 86.—From B. Cavalieri's *Exercitationes* (1647), p. 268

We shall use the following abbreviations for the designation of tracts which were added to one or another of the different editions of the *Clavis mathematicae*:

Eq. = *De Aequationum affectarum resolutione in numeris*

Eu. = *Elementi decimi Euclidis declaratio*

So. = *De Solidis regularibus, tractatus*

An. = *De Anatocismo, sive usura composita*

Fa. = *Regula falsae positionis*

Ar. = *Theorematum in libris Archimedis de sphaera & cylindro declaratio*

Ho. = *Horologia scioterica in plano, Geometricè delineandi modus*

In 1632 there appeared, in London, Oughtred's *The Circles of Proportion*, which was brought out again in 1633 with an *Addition unto the Vse of the Instrument called the Circles of Proportion*.¹ Another edition bears the date 1660. In 1657 was published Oughtred's *Trigonometria*,² in Latin, and his *Trigonometrie*, an English translation.

We have arranged Oughtred's symbols, as found in his various works, in tabular form.³ The texts referred to are placed at the head of the table, the symbols in the column at the extreme left. Each number in the table indicates the page of the text cited at the head of the column containing the symbol given on the left. Thus, the notation $::$ in geometrical proportion occurs on page 7 of the *Clavis* of 1648. The page assigned is not always the first on which the symbol occurs in that volume.

¹ In our tables this *Addition* is referred to as *Ad*.

² In our tables *Ca.* stands for *Canones sinuum tangentium*, etc., which is the title for the tables in the *Trigonometria*.

³ These tables were first published, with notes, in the *University of California Publications in Mathematics*, Vol. I, No. 8 (1920), p. 171-86.

181. OUGHTRED'S MATHEMATICAL SYMBOLS

186. Historical notes¹ to the tables in §§ 181–85:

1. All the symbols, except “Log,” which we saw in the 1660 edition of the *Circles of Proportion*, are given in the editions of 1632 and 1633.

2. In the first half of the seventeenth century the notation for decimal fractions engaged the attention of mathematicians in England as it did elsewhere (see §§ 276–89). In 1608 an English translation of Stevin’s well-known tract was brought out, with some additions, in London by Robert Norton, under the title, *Disme: The Art of Tenths, or, Decimall Arithmetike* (§ 276). Stevin’s notation is followed also by Henry Lyte in his *Art of Tens or Decimall Arithmetique* (London, 1619), and in *Johnsons Arithmetick* (2d ed.; London, 1633), where 3576.725 is

written $3576\overset{1}{\overset{2}{\overset{3}{|}}}725$. William Purser in his *Compound Interest and Annuities* (London, 1634), p. 8, uses the colon (:) as the separator, as did Adrianus Metius in his *Geometriae practicae pars I et II* (Lugd., 1625), p. 149, and Rich. Balam in his *Algebra* (London, 1653), p. 4. The decimal point or comma appears in John Napier’s *Rabdologia* (Edinburgh, 1617). Oughtred’s notation for decimals must have delayed the general adoption of the decimal point or comma.

3. This mixture of the old and the new decimal notation occurs in the *Key* of 1694 (*Notes*) and in Gilbert Clark’s *Oughtredus explicatus*² only once; no reference is made to it in the table of errata of either book. On Oughtred’s *Opuscula mathematica hactenus inedita*, the mixed notation 128,⁵⁷ occurs on p. 193 fourteen times. Oughtred’s regular notation 128|⁵⁷ hardly ever occurs in this book. We have seen similar mixed notations in the *Miscellanies: or Mathematical Lucubrations, of Mr. Samuel Foster, Sometime publike Professor of Astronomie in Gresham Colledge, in London*, by John Twysden (London, 1659), p. 13 of the “Observationes eclipsium”; we find there 32.466, 31.008.

4. The dot (.), used to indicate ratio, is not, as claimed by some writers, used by Oughtred for division. Oughtred does not state in his book that the dot (.) signifies division. We quote from an early and a late edition of the *Clavis*. He says in the *Clavis* of 1694, p. 45, and in the one of 1648, p. 30, “to continue ratios is to multiply them as if they were fractions.” Fractions, as well as divisions, are indicated by a horizontal line. Nor does the statement from the *Clavis* of 1694, p. 20, and the edition of 1648, p. 12, “In Division, as the Divisor is to Unity, so is the Dividend to the Quotient,” prove that he looked upon ratio as an indicated division. It does not do so any more than the sentence from the *Clavis* of 1694, and the one of 1648, p. 7, “In Multiplication, as 1 is to either of the factors, so is the other to the Product,” proves that he considered ratio an indicated multiplication. Oughtred says (*Clavis* of 1694, p. 19, and the one of 1631, p. 8): “If Two Numbers stand one above another with a Line drawn between them, ’tis as much as to say, that the upper is to be divided by the under; as $\frac{12}{4}$ and $\frac{5}{12}$.”

¹ N. 1 refers to the *Circles of Proportion*. The other notes apply to the superscripts found in the column, “Meanings of Symbols.”

² This is not a book written by Oughtred, but merely a commentary on the *Clavis*. Nevertheless, it seemed desirable to refer to its notation, which helps to show the changes then in progress.

In further confirmation of our view we quote from Oughtred's letter to W. Robinson: "Division is wrought by setting the divisor under the dividend with a line between them."¹

5. In Gilbert Clark's *Oughtredus explicatus* there is no mark whatever to separate the characteristic and mantissa. This is a step backward.

6. Oughtred's language (*Clavis* of 1652, p. 21) is: "Ut 7.4: 12.9 vel 7.7-3: 12.12-3. Arithmeticè proportionales sunt." As later in his work he does not use arithmetical proportion in symbolic analysis, it is not easy to decide whether the symbols just quoted were intended by Oughtred as part of his algebraic symbolism or merely as punctuation marks in ordinary writing. Oughtred's notation is adopted in the article "Caractere" of the *Encyclopédie méthodique (mathématiques)*, Paris: Liège, 1784 (see § 249).

7. In the publications referred to in the table, of the years 1648 and 1694, the use of : to signify ratio has been found to occur only once in each copy; hence we are inclined to look upon this notation in these copies as printer's errors. We are able to show that the colon (:) was used to designate geometric ratio some years before 1657, by at least two authors, Vincent Wing the astronomer, and a schoolmaster who hides himself behind the initials "R.B." Wing wrote several works.

8. Oughtred's notation $A.B::C.D$, is the earliest serviceable symbolism for proportion. Before that proportions were either stated in words as was customary in rhetorical modes of exposition, or else was expressed by writing the terms of the proportion in a line with dashes or dots to separate them. This practice was inadequate for the needs of the new symbolic algebra. Hence Oughtred's notation met with ready acceptance (see §§ 248-59).

9. We have seen this notation only once in this book, namely, in the expression $R.S.=3.2$.

10. Oughtred says (*Clavis* of 1694, p. 47), in connection with the radical sign, "If the Power be included between two Points at both ends, it signifies the universal Root of all that Quantity so included; which is sometimes also signified by b and r , as the \sqrt{b} is the Binomial Root, the \sqrt{r} the Residual Root." This notation is in no edition strictly adhered to; the second : is often omitted when all the terms to the end of the polynomial are affected by the radical sign or by the sign for a power. In later editions still greater tendency to a departure from the original notation is evident. Sometimes one dot takes the place of the two dots at the end; sometimes the two end dots are given, but the first two are omitted; in a few instances one dot at both ends is used, or one dot at the beginning and no symbol at the end; however, these cases are very rare and are perhaps only printer's errors. We copy the following illustrations:

$Q : A - E$: est $Aq - 2AE + Eq$, for $(A - E)^2 = A^2 - 2AE + E^2$ (from *Clavis* of 1631, p. 45)

$\frac{1}{2}BCq \pm \sqrt{q} : \frac{1}{4}BCqq - CMqq = \frac{BAq}{CAq}$, for $\frac{1}{2}BC^2 \pm \sqrt{(\frac{1}{4}BC^4 - CM^4)} = BA^2$ or CA^2
(from *Clavis* of 1648, p. 106)

$\sqrt{q} : BA + CA = BC + D$, for $\sqrt{(BA + CA)} = BC + D$ (from *Clavis* of 1631, p. 40)

$\frac{AB}{2} + \sqrt{q} \frac{ABq}{4} - \frac{C \times S}{R} : = A$, for $\frac{AB}{2} + \sqrt{\left(\frac{AB^2}{4} - \frac{C \times S}{R}\right)} = A$. (from *Clavis* of 1652, p. 95)

¹ Rigaud, *Correspondence of Scientific Men of the Seventeenth Century*, Vol. I (1841), Letter VI, p. 8.

$Q.Hc + Ch$: for $(Hc + Ch)^2$ (from *Clavis* of 1652, p. 57)

$Q.A - X =$, for $(A - X)^2 =$ (from *Clavis* of 1694, p. 97)

$\frac{B}{2} + r.u. \frac{Bq}{4} - CD. = A$, for $\frac{B}{2} + \sqrt{\left(\frac{B^2}{4} - CD\right)} = A$ (from *Oughtredus explicatus* [1682], p. 101)

11. These notations to signify aggregation occur very seldom in the texts referred to and may be simply printer's errors.

12. Mathematical parentheses occur also on p. 75, 80, and 117 of G. Clark's *Oughtredus explicatus*.

13. In the *Clavis* of 1631, p. 2, it says, "Signum additionis siue affirmationis, est + plus" and "Signum subductionis, siue negationis est - minus." In the edition of 1694 it says simply, "The Sign of Addition is + more" and "The Sign of Subtraction is - less," thereby ignoring, in the definition, the double function played by these symbols.

14. In the errata following the Preface of the 1694 edition it says, for "more or mo. r. [lead] plus or pl.;" for less or le. r.[lead] minus or mi."

15. Oughtred's *Clavis mathematicae* of 1631 is not the first appearance of \times as a symbol for multiplication. In Edward Wright's translation of John Napier's *Descriptio*, entitled *A Description of the Admirable Table of Logarithms* (London, 1618), the letter "X" is given as the sign of multiplication in the part of the book called "An Appendix to the Logarithms, shewing the practise of the calculation of Triangles, etc."

The use of the letters x and X for multiplication is not uncommon during the seventeenth and beginning of the eighteenth centuries. We note the following instances: Vincent Wing, *Doctrina theorica* (London, 1656), p. 63; John Wallis, *Arithmetica infinitorum* (Oxford, 1655), p. 115, 172; *Moore's Arithmetick in two Books*, by Jonas Moore (London, 1660), p. 108; Antoine Arnauld, *Novveaux elemens de geometrie* (Paris, 1667), p. 6; Lord Brouncker, *Philosophical Transactions*, Vol. II (London, 1668), p. 466; *Exercitatio geometrica*, auctore Laurentio Lorenzino, Vincentii Viviani discipulo (Florence, 1721). John Wallis used the \propto in his *Elenchus geometriae Hobbianae* (Oxoniae, 1655), p. 23.

16. in as a symbol of multiplication carries with it also a collective meaning; for example, the *Clavis* of 1652 has on p. 77, "Erit $\frac{1}{2}Z + \frac{1}{2}B$ in $\frac{1}{2}Z - \frac{1}{2}B = \frac{1}{4}Zq - \frac{1}{4}Bq$."

17. That is, the line AB squared.

18. These capital letters precede the expression to be raised to a power. Seldom are they used to indicate powers of monomials. From the *Clavis* of 1652, p. 65, we quote:

$${}^{\circ}Q : A + E : +Eq = 2Q : \frac{1}{2}A + E : + 2Q. \frac{1}{2}A , "$$

$$\text{i.e., } (A + E)^2 + E^2 = 2(\frac{1}{2}A + E)^2 + 2\left(\frac{A}{2}\right)^2 .$$

19. L and l stand for the same thing, "side" or "root," l being used generally when the coefficients of the unknown quantity are given in Hindu-Arabic numerals, so that all the letters in the equation, viz., l , q , c , qg , qc , etc., are small letters. The *Clavis* of 1694, p. 158, uses L in a place where the Latin editions use l .

20. The symbol \sqrt{u} does not occur in the *Clavis* of 1631 and is not defined in the later editions. The following throws light upon its significance. In the 1631 edition, chap. xvi, sec. 8, p. 40, the author takes $\sqrt{qBA} + B = CA$, gets from it $\sqrt{qBA} = CA - B$, then squares both sides and solves for the unknown A . He passes

next to a radical involving two terms, and says: "Item \sqrt{q} vniuers : $BA + CA : - D = BC$: vel per transpositionem $\sqrt{q} : BA + CA = BC + D$ "; he squares both sides and solves for A . In the later editions he writes " \sqrt{u} " in place of " \sqrt{q} vniuers :"

21. The sum $Z = A + E$ and the difference $X = A - E$ are used later in imitation of Oughtred by Samuel Foster in his *Miscellanies* (London, 1659), "Of Projection," p. 8, and by Sir Jonas Moore in his *Aithmetick* (3d ed.; London, 1688), p. 404; John Wallis in his *Operum mathematicorum pars prima* (Oxford, 1657), p. 169, and other parts of his mathematical writings.

22. Harriot's symbols $>$ for "greater" and $<$ for "less" were far superior to the corresponding symbols used by Oughtred.

23. This notation for "less than" in the *Ho.* occurs only in the explanation of "Fig. *EE.*" In the text (chap. ix) the regular notation explained in *Eu.* is used.

24. The symbol ∞ so closely resembles the symbol ∞ which was used by John Wallis in his *Operum mathematicorum pars prima* (Oxford, 1657), p. 208, 247, 334, 335, that the two symbols were probably intended to be one and the same. It is difficult to assign a good reason why Wallis, who greatly admired Oughtred and was editor of the later Latin editions of his *Clavis mathematicae*, should purposely reject Oughtred's ∞ and intentionally introduce ∞ as a substitute symbol.

25. Von Braunmühl, in his *Geschichte der Trigonometrie* (2. Teil; Leipzig, 1903), p. 42, 91, refers to Oughtred's *Trigonometria* of 1657 as containing the earliest use of abbreviations of trigonometric functions and points out that a half-century later the army of writers on trigonometry had hardly yet reached the standard set by Oughtred. This statement must be modified in several respects (see §§ 500-526).

26. This reference is to the English edition, the *Trigonometrie* of 1657. In the Latin edition there is printed on p. 5, by mistake, s instead of s versus. The table of errata makes reference to this misprint.

27. The horizontal line was printed beneath the expression that was being crossed out. Thus, on p. 68 of the *Clavis* of 1631 there is:

$$\begin{aligned} BGq - \underline{BGq \times 2BK \times BD} + BKq \times BDq \\ = BGq \times BDq + BGq \times BKq - \underline{BGq \times 2BK \times BD} + BGq \times 4CAq. \end{aligned}$$

28. This notation, says Oughtred, was used by ancient writers on music, who "are wont to connect the terms of ratios, either to be continued" as in $\frac{3}{2} \times \frac{4}{3} = 2$, "or diminish'd" as in $\frac{3}{2} \div \frac{4}{3} = \frac{9}{8}$.

29. See n. 15.

30. *Cru* and *crur* are abbreviations for *crurum*, side of a rectangle or right triangle. Hence Z *cru* means the sum of the sides, X *cru*, the difference of the sides.

187. Oughtred's recognition of the importance of notation is voiced in the following passage:

"... Which Treatise being not written in the usuall synthetical manner, nor with verbous expressions, but in the inventive way of Analitice, and with symboles or notes of things instead of words, seemed unto many very hard; though indeed it was but their owne diffidence, being scared by the newness of the delivery; and not any

difficulty in the thing it selfe. For this specious and symbolically manner, neither racketh the memory with multiplicity of words, nor chargeth the phantasie with comparing and laying things together; but plainly presenteth to the eye the whole course and processe of every operation and argumentation."¹

Again in his *Circles of Proportion* (1632), p. 20:

"This manner of setting downe theoremes, whether they be Proportions, or Equations, by Symboles or notes of words, is most excellent, artificiall, and doctrinall. Wherefore I earnestly exhort every one, that desireth though but to looke into these noble Sciences Mathematicall, to accustome themselves unto it: and indeede it is easie, being most agreeable to reason, yea even to sence. And out of this working may many singular consecutaries be drawne: which without this would, it may be, for ever lye hid."

ENGLISH: THOMAS HARRIOT
(1631)

188. Thomas Harriot's *Artis analyticae praxis* (London, 1631) appeared as a posthumous publication. He used small letters in place of Vieta's capitals, indicated powers by the repetition of factors, and invented > and < for "greater" and "less."

Harriot used a very long sign of equality \equiv . The following quotation shows his introduction of the now customary signs for "greater" and "smaller" (p. 10):

"Comparationis signa in sequentibus vsurpanda.

Aequalitatis \equiv ut $a \equiv b$. significet a aequalem ipi b .

Maioritatis $>$ ut $a > b$. significet a maiorem quam b .

Minoritatis $<$ ut $a < b$ significet a minorem quam b ."

Noteworthy is the notation for multiplication, consisting of a vertical line on the right of two expressions to be multiplied together of which one is written below the other; also the notation for complex fractions in which the principal fractional line is drawn double. Thus (p. 10):

$$\frac{\frac{ac}{b}}{b} \Bigg| \equiv \frac{acb}{b} \equiv ac.$$

$$\frac{\frac{aaa}{b}}{d} \equiv \frac{aaa}{bd}.$$

¹ William Oughtred, *The Key of the Mathematicks* (London, 1647), Preface.

Harriot places a dot between the numerical coefficient and the other factors of a term. Excepting only a very few cases which seem to be printer's errors, this notation is employed throughout. Thus (p. 60):

"Aequationis $aaa-3.baa+3.bba\equiv+2.bbb$ est 2.b. radix
radici quaesititiae a . aequalis."

Probably this dot was not intended as a sign of multiplication, but simply a means of separating a numeral from what follows, according to a custom of long standing in manuscripts and early printed books.

On the first twenty-six pages of his book, Harriot frequently writes all terms on one side of an equation. Thus (p. 26):

"Posito igitur $cdf=aaa$. est $aaa-cdf$ $\left| \begin{array}{c} \\ a+b \end{array} \right| \equiv 0$

Est autem ex genesi $aaa-cdf$ $\left| \begin{array}{c} \\ a+b \end{array} \right| \equiv aaaa+baaa-cdfa-bcdf$.

quae est aequatio originalis hic designata.

Ergo . . . $aaaa+baaa-cdfa-bcdf. \equiv 0$."

Sometimes Harriot writes underneath a given expression the result of carrying out the indicated operations, using a brace, but without using the regular sign of equality. This is seen in Figure 87. The first equation is $52 = -3a + aaa$, where the vowel a represents the unknown. Then the value of a is given by Tartaglia's formula, as $\sqrt[3]{26 + \sqrt{675}} + \sqrt[3]{26 - \sqrt{675}} = 4$. Notice that " $\sqrt[3]{}$ " indicates that the cube root is taken of the binomial $26 + \sqrt{675}$.

In Figure 88 is exhibited Harriot's use of signs of equality placed vertically and expressing the equality of a polynomial printed above a horizontal line with a polynomial printed below another horizontal line. This exhibition of the various algebraic steps is clever.

FRENCH: PIERRE HÉRIGONE
(1634, 1644)

189. A full recognition of the importance of notation and an almost reckless eagerness to introduce an exhaustive set of symbols is exhibited in the *Cursus mathematicus* of Pierre Hérigone, in six volumes, in Latin and French, published at Paris in 1634 and, in a second edition, in 1644. At the beginning of the first volume is given

In duabus antecedentibus æquationibus accidit interdum binomia cubica solutionis radicalibus implicata explicari posse per radices itidem binomias, quæ per summam vel differentiam constituent tandem radicem simplicem æquationis explicatoriam. Huius generis solutionum exempla sunt quæ sequuntur.

$$\begin{array}{l}
 52 = 3 \cdot a + a a a \dots a = 4. \\
 a = \sqrt{3 \cdot 26} + \sqrt{675} + \sqrt{3 \cdot 26} - \sqrt{675} \\
 \quad \quad \quad 2. + \sqrt{3 \cdot \dots} + \dots 2 - \sqrt{3 \cdot \dots} \\
 \quad \quad \quad 4.
 \end{array}$$

$$\begin{array}{l}
 270 = 9 \cdot a + a a a \dots a = 6. \\
 a = \sqrt{3 \cdot 18252} + 135 - \sqrt{3 \cdot 18252} - 135. \\
 \quad \quad \quad \sqrt{12 + 3 \dots} \dots \sqrt{12} - 3. \\
 \quad \quad \quad 6.
 \end{array}$$

$$\begin{array}{l}
 40 = 6 \cdot a + a a a \dots a = 4. \\
 a = \sqrt{3 \cdot 20} + \sqrt{392} + \sqrt{3 \cdot 20} - \sqrt{392} \\
 \quad \quad \quad 2. + \sqrt{2 \cdot \dots} + \dots 2 - \sqrt{2 \cdot \dots}
 \end{array}$$

FIG. 87.—From Thomas Harriot's *Artis analyticae praxis* (1631), p. 101

Lemma.

Si dari possit radix aliqua æquationis radici a . æqualis, quæ radicibus b . c . d . inæqualis sit, esto illa f . siue alia quæcunque.

$$\begin{aligned} \text{Posito igitur } f &= a. \text{ erit } ffff - bfff + bcff \\ &\quad - cfff + bddf \\ &\quad - dfff + cdff - bcdf : \\ &\quad + ffff - bfff + bcff \\ &\quad \quad - cfff + bddf \\ &\quad \quad - dfff + cdff = + bcdf. \end{aligned}$$
$$\begin{array}{r} \text{Ergo} \dots +2.f f f f - 2.e f f f + 2.c d f f - 2.d f f f \\ \hline \hline +2.b f f f - 2.b c f f + 2.b c d f - 2.b d f f \end{array}$$
$$\text{Hocet} \dots \dots \dots \frac{+ f f f f - c f f f + c d f f - d f f f}{+ b f f f - b c f f + b c d f - b d f f} \\ + f f f - c f f + d c f - d f f \Big|_f = + f f f - c f f + c d f - d f f \Big|_b$$

Ergo $f \equiv b$. Quod est contra Lemmatis hypothesin.

Non est igitur $f = 4$, ut erat positum. Quod de alia quacunque ex simili deductione demonstrandum est.

FIG. 88.—From Thomas Harriot's *Artis analyticae praxis* (1631), p. 65

an explanation of the symbols. As found in the 1644 edition, the list is as follows:

$+$ plus	is, signifie le plurier
\sim minus	$2 2$ aequalis
$\cdot \sim$: differentia	$3 2$ maior
4 inter se, <i>entrêlles</i>	$2 3$ minor
$4 n$ in, <i>en</i>	$\frac{1}{3}$ tertia pars
$4 ntr.$ inter, <i>entre</i>	$\frac{1}{4}$ quarta pars
11 vel, <i>ou</i>	$\frac{2}{3}$ duae tertiae
π , ad, <i>à</i>	a, b, $11 ab$ rectangulum quod sit
$5 <$ pentagonum, penta-	ductu A in B
gone	\cdot est punctum
$6 <$ hexagonum	$—$ est recta linea
$\sqrt{\cdot} 4 <$ latus quadrati	$<, \angle$ est angulus
$\sqrt{\cdot} 5 <$ latus pentagoni	\lrcorner est angulus rectus
a^2 A quadratum	\odot est circulus
a^3 A cubus	$\oslash \oslash$ est pars circumfer-
a^4 A quadrato-quadratũ.	entiae circuli
et sic infinitum.	\oslash, \oslash est segmentu circuli
$=$ parallela	\triangle est triangulum
\perp perpendicularis	\square est quadratum
$\cdot \cdot$ est nota genitini, <i>signi-</i>	\square est rectangulum
<i>fie (de)</i>	\diamond est parallelogrammum
; est nota numeri plural-	\diamond piped. est parallelepipedum

In this list the symbols that are strikingly new are those for equality and inequality, the \sim as a minus sign, the $—$ being made to represent a straight line. Novel, also, is the expression of exponents in Hindu-Arabic numerals and the placing of them to the right of the base, but not in an elevated position. At the beginning of Volume VI is given a notation for the aggregation of terms, in which the comma plays a leading rôle:

" $\square \cdot a^2 \sim 5a + 6, a \sim 4$: virgula, la virgule, distinguit multiplicatorem $a \sim 4$ *d* multiplicação $a^2 \sim 5a + 6$.

Ergo $\square \cdot 5 + 4 + 3, 7 \sim 3: \sim 10$, est 38."

Modern: The rectangle $(a^2 - 5a + 6)(a - 4)$,
Rectangle $(5 + 4 + 3)(7 - 3) - 10 = 38$.

"*hg* π *ga* $2|2$ *hb* π *bd*, signifi. *HG* est *ad GA*, *vt HB* *ad BD*."

D'EVCLIDE, LIV. I. 39

THEOR. XXXIII. PROPOS. XLVII.

Aux triangles rectangles, le quarré du costé qui
soustient l'angle droit, est égal aux quarez des
costez qui contiennent le même angle droit.

Hypoth.
an $\triangle abc$
 $\angle bac$ est \perp ,

FIG. 89.—From P. Herigone, *Cursus mathematicus*, Vol. VI (1644); proof of the Pythagorean theorem.

Modern: $hg : ga = hb : bd$.

" $\sqrt{\cdot}16+9$ est 5, se pormoit de serire plus distinctement ainsi ,
 $\sqrt{\cdot}(16+9)$ 11 $\sqrt{\cdot}\overline{16+9}$, est 5: $\sqrt{\cdot}9$, +4, sont
 7: $\sqrt{\cdot}9$, + $\sqrt{\cdot}4$ sont 5: "

Modern: $\sqrt{\cdot}16+9$ is 5, can be written more clearly thus,
 $\sqrt{\cdot}(16+9)$ or $\sqrt{\cdot}\overline{16+9}$, is 5; $\sqrt{\cdot}9$, +4, are 7;
 $\sqrt{\cdot}9$, + $\sqrt{\cdot}4$ are 5.

FRENCH: JAMES HUME

(1635, 1636)

190. The final development of the modern notation for positive integral exponents took place in mathematical works written in French. Hume was British by birth. His *Le traité d'algèbre* (Paris, 1635) contains exponents and radical indexes expressed in Roman numerals. In Figure 90 we see that in 1635 the plus (+) and minus (−) signs were firmly established in France. The idea of writing exponents without the bases, which had been long prevalent in the writings of Chuquet, Bombelli, Stevin, and others, still prevails in the 1635 publication of Hume. Expressing exponents in Roman symbols made it possible to write the exponent on the same line with the coefficient without confusion of one with the other. The third of the examples in Figure 90 exhibits the multiplication of $8x^2+3x$ by $10x$, yielding the product $80x^3+30x^2$.

The translation of part of Figure 91 is as follows: "Example: Let there be two numbers $\sqrt[9]{9}$ and $\sqrt[8]{8}$, to reduce them it will be necessary to take the square of $\sqrt[8]{8}$, because of the II which is with 9, and the square of the square of $\sqrt[9]{9}$ and you obtain $\sqrt[6561]{9}$ and $\sqrt[64]{8}$

$\sqrt[8]{8}$ to $\sqrt[64]{8}$	$\sqrt[3]{3}$ to $\sqrt[8]{8}$ [should be $\sqrt[9]{9}$]
$\sqrt[9]{9}$ to $\sqrt[729]{9}$	$\sqrt[2]{2}$ to $\sqrt[9]{9}$ [should be $\sqrt[8]{8}$]
	$\sqrt[3]{3}$ to $\sqrt[9]{9}$
	$\sqrt[2]{2}$ to $\sqrt[32]{2}$."

The following year, Hume took an important step in his edition of *L'algèbre de Viète* (Paris, 1636), in which he wrote A^{iii} for A^3 . Except for the use of the Roman numerals one has here the notation used by Descartes in 1637 in his *La géométrie* (see § 191).

FRENCH: RENÉ DESCARTES
(1637)

191. Figure 92 shows a page from the first edition of Descartes' *La géométrie*. Among the symbolic features of this book are: (1) the use of small letters, as had been emphasised by Thomas Harriot;

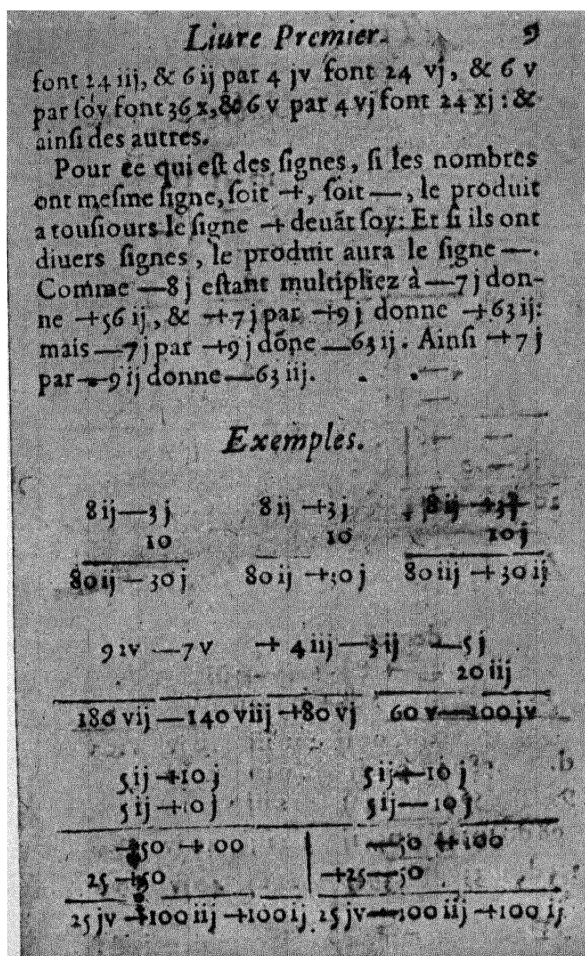

FIG. 90.—Roman numerals for unknown numbers in James Hume, *Algèbre* (Paris, 1635).

(2) the writing of the positive integral exponents in Hindu-Arabic numerals and in the position relative to the base as is practiced today,

except that aa is sometimes written for a^2 ; (3) the use of a new sign of equality, probably intended to represent the first two letters in the word *aequalis*, but apparently was the astronomical sign, ♄ taurus,

angle, iufques a O, en forte qu'N O foit efgale a N L, la toute OM eft \propto la ligne cherchée. Et elle s'exprime en cete forte

$$\propto \propto \frac{1}{2}a + \sqrt{\frac{1}{4}aa + bb}.$$

Que fi iay $y \propto - \frac{1}{2}a + \sqrt{\frac{1}{4}aa + bb}$, & qu'y foit la quantité qu'il faut trouuer, ie fais le mefme triangle rectangle N L M, & de fa baze M N i'ofte N P efgale a N L, & le refte P M eft y la racine cherchée. De façon que iay $y \propto - \frac{1}{2}a + \sqrt{\frac{1}{4}aa + bb}$. Et tout de mefme fi i'aurois $x \propto - \frac{1}{2}a + \sqrt{\frac{1}{4}aa + bb}$. P M feroit x. & i'aurois

$$x \propto \sqrt{-\frac{1}{2}a + \sqrt{\frac{1}{4}aa + bb}}; \text{ \& ainfi des autres.}$$

Enfin fi i'ay

$$\propto \propto a\propto - bb;$$

ie fais N L efgale à $\frac{1}{2}a$, & L M efgale à b cõme deuât, puis, au lieu de ioindre les points M N, ie tire M Q R parallele a L N. & du centre N par L ayant defcrit vn cercle qui la coupe aux points Q & R, la ligne cherchée \propto eft M Q, oubiẽ M R, car en ce cas elle s'exprime en deux façons, a fçauoir $\propto \propto \frac{1}{2}a + \sqrt{\frac{1}{4}aa - bb}$,

$$\text{ \& } \propto \propto \frac{1}{2}a - \sqrt{\frac{1}{4}aa - bb}.$$

Et fi le cercle, qui ayant fon centre au point N, paffe par le point L, ne coupe ny ne touche la ligne droite M Q R, il n'y a aucune racine en l'Equation, de façon qu'on peut affurer que la construction du problemẽ proposẽ eft impossible.

Au

placed horizontally, with the opening facing to the left; (4) the uniting of the vinculum with the German radical sign $\sqrt{}$, so as to give $\sqrt{}$, an adjustment generally used today.

The following is a quotation from Descartes' text (ed., Paris, 1886, p. 2): "Mais souvent on n'a pas besoin de tracer ainsi ces lignes sur le papier, et il suffit de les désigner par quelques lettres, chacune par une seule. Comme pour ajouter le ligne BD à GH , je nomme l'une a et l'autre b , et écris $a+b$; et $a-b$ pour soustraire b de a ; et ab pour les multiplier l'une par l'autre; et $\frac{a}{b}$ pour diviser a par b ; et aa ou a^2 pour multiplier a par soi-même; et a^3 pour le multiplier encore une fois par a , et ainsi à l'infini."

The translation is as follows: "But often there is no need thus to trace the lines on paper, and it suffices to designate them by certain letters, each by a single one. Thus, in adding the line BD to GH , I designate one a and the other b , and write $a+b$; and $a-b$ in subtracting b from a ; and ab in multiplying the one by the other; and $\frac{a}{b}$ in dividing a by b ; and aa or a^2 in multiplying a by itself; and a^3 in multiplying it once more again by a , and thus to infinity."

ENGLISH: ISAAC BARROW
(1655, 1660)

192. An enthusiastic admirer of Oughtred's symbolic methods was Isaac Barrow,¹ who adopted Oughtred's symbols, with hardly any changes, in his Latin (1655) and his English (1660) editions of *Euclid*. Figures 93 and 94 show pages of Barrow's *Euclid*.

ENGLISH: RICHARD RAWLINSON
(1655-68)

193. Sometime in the interval 1655-68 Richard Rawlinson, of Oxford, prepared a pamphlet which contains a collection of lithographed symbols that are shown in Figure 95, prepared from a crude freehand reproduction of the original symbols. The chief interest lies in the designation of an angle of a triangle and its opposite side by the same letter—one a capital letter, the other letter small. This simple device was introduced by L. Euler, but was suggested many years earlier by Rawlinson, as here shown. Rawlinson designated spherical

¹ For additional information on his symbols, see §§ 456, 528.

triangles by conspicuously rounded letters and plane triangles by letters straight in part.

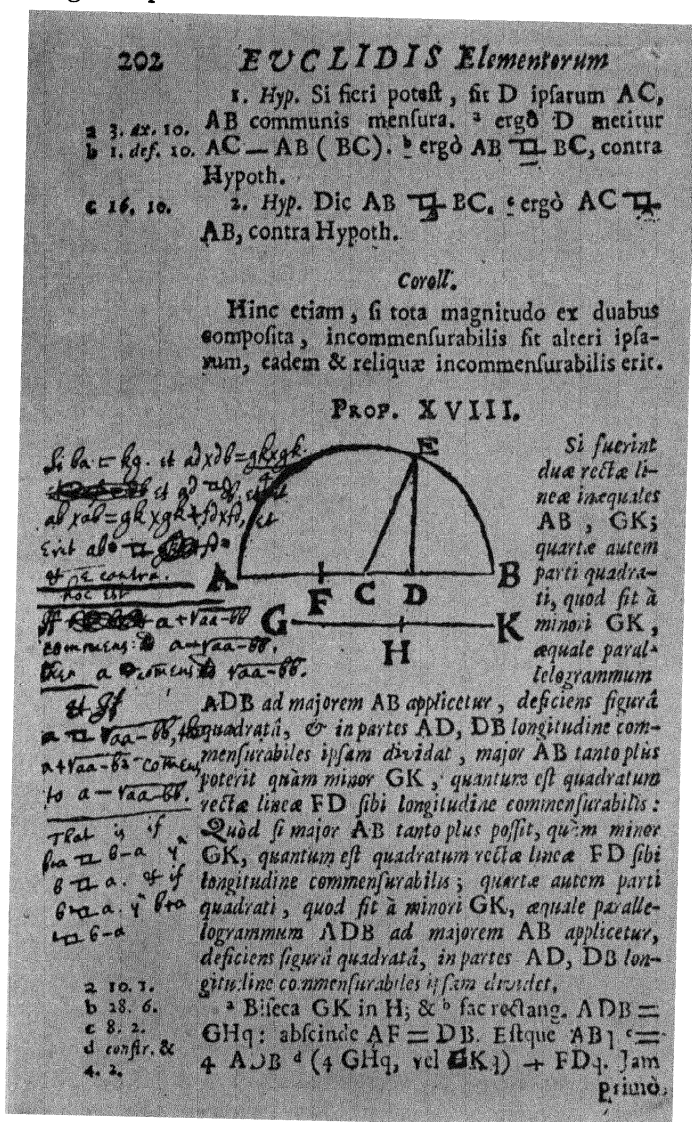

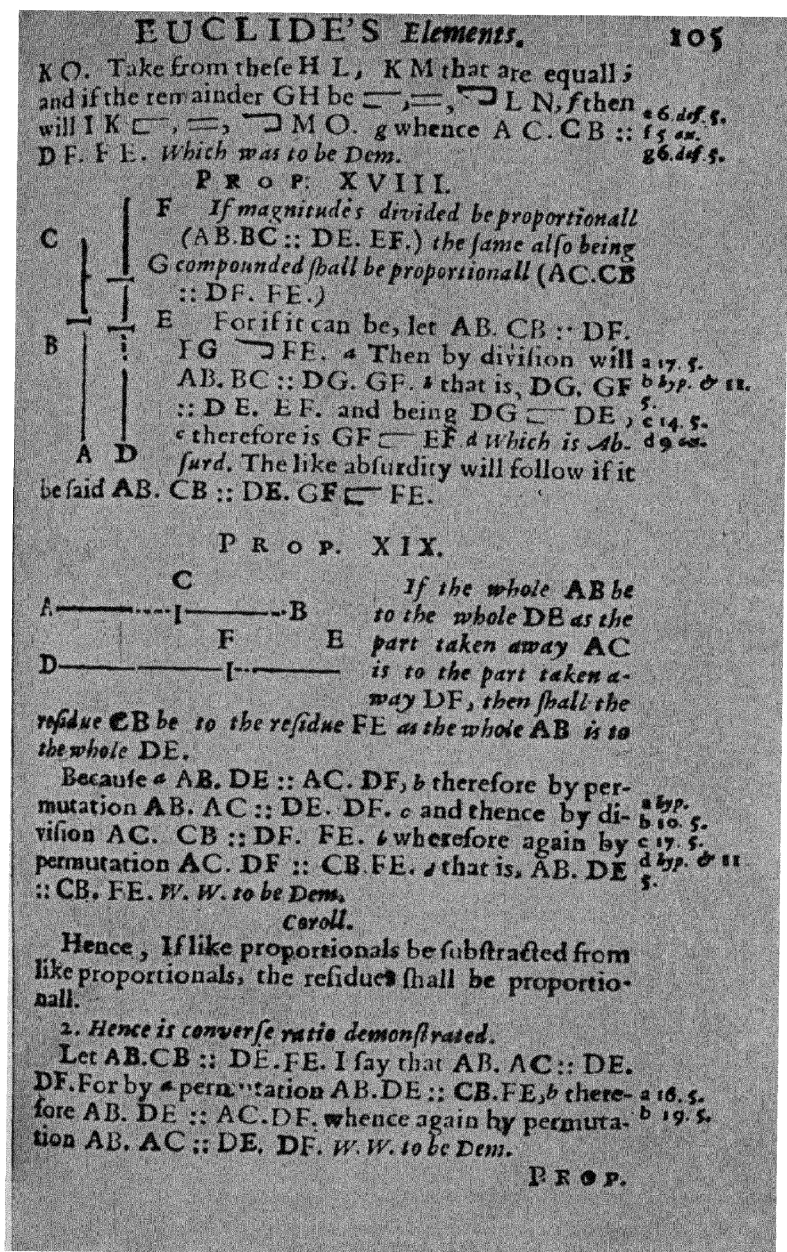

FIG. 93.—Latin edition (1655) of Barrow's *Euclid*. Notes by Isaac Newton. (Taken from *Isaac Newton: A Memorial Volume* [ed. W. J. Greenstreet; London, 1927], p. 168.)

FIG. 94.—English edition of Isaac Barrow's *Euclid*

SWISS: JOHANN HEINRICH RAHN

(1659)

194. Rahn published in 1659 at Zurich his *Teutsche Algebra*, which was translated by Thomas Brancker and published in 1668 at London, with additions by John Pell. There were some changes in the symbols as indicated in the following comparison:

Meaning	German Edition, 1659	English Edition, 1668
1. Multiplication.....	* (p. 7)	Same (p. 6)
2. $a+b$ times $a-b$	$\begin{array}{ l} a+b \\ a-b \end{array}$ (p. 14)	Same (p. 12)
3. Division.....	\div (p. 8)	Same (p. 7)

14. Nos. in outer column <i>not</i> referring to numbers in middle column.....	1, 2, 3, etc. (p. 3)	1, 2, 3, etc. (p. 3)

REMARKS ON THESE SYMBOLS

No. 1.—Rahn's sign * for multiplication was used the same year as Brancker's translation, by N. Mercator, in his *Logarithmotechnia* (London, 1668), p. 28.

No. 4.—If the lowest common multiple of abc and ad is required, Rahn writes $\frac{abc}{ad} = \frac{bc}{d}$; then $\frac{abc}{ad} \times \frac{bc}{d}$ yields $abcd$ in each of the two cross-multiplications.

No. 8.—Rahn's and Brancker's modes of indicating the higher powers and roots differ in principle and represent two different procedures which had been competing for supremacy for several centuries. Rahn's $\sqrt[6]{gc}$ means the sixth root, $2 \times 3 = 6$, and represents the Hindu idea. Brancker's *cubo-cubick* root means the "sixth root," $3 + 3 = 6$, and represents the Diophantine idea.

No. 9.—In both editions occur both \therefore and \therefore , but \therefore prevails in the earlier edition; \therefore prevails in the later.

No. 10.—The symbols indicate that the operation is impossible or, in case of a root, that it is imaginary.

No. 11.—The use of the comma is illustrated thus: The marginal column (1668, p. 54) gives "6, 1," which means that the sixth equation " $Z = A$ " and the first equation " $A = 6$ " yield $Z = 6$.

No. 12.—For example, if in a right triangle h , b , c , we know only $b-c$, then one of the three sides, say c , is indeterminate.

Page 73 of Rahn's *Teutsche Algebra* (shown in Fig. 96) shows: (1) the first use of \div in print, as a sign of division; (2) the Archimedean spiral for involution; (3) the double epsilon for evolution; (4) the

use of capital letters B, D, E , for given numbers, and small letters a, b , for unknown numbers; (5) the $*$ for multiplication; (6) the first use of \therefore for "therefore"; (7) the three-column arrangement of which the left column contains the directions, the middle the numbers of

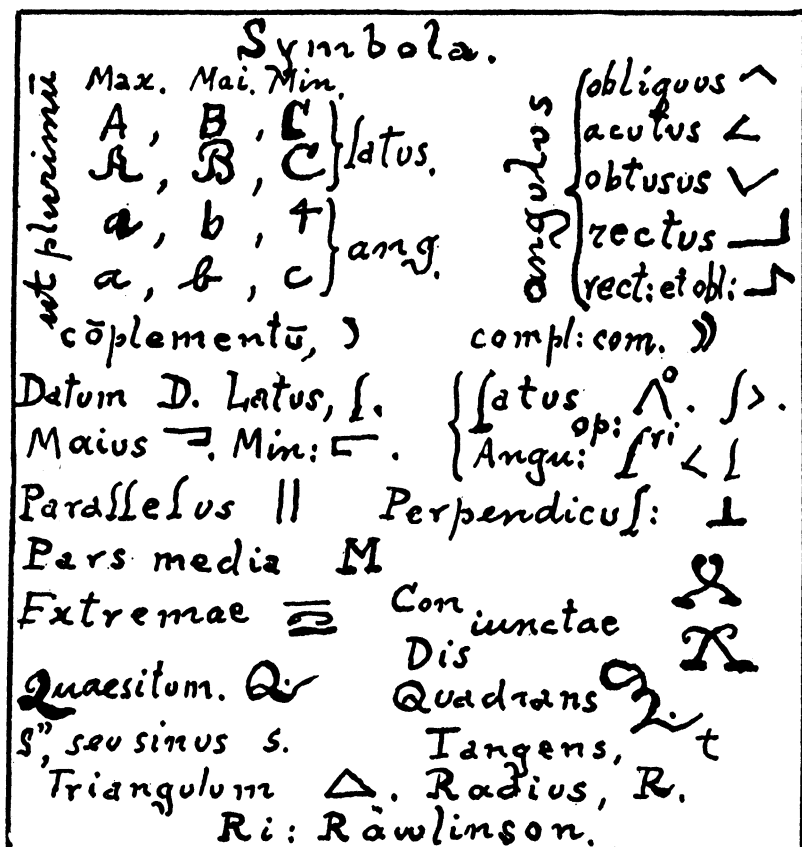

FIG. 95.—Freehand reproduction of Richard Rawlinson's symbols

the lines, the right the results of the operations. Thus, in line 3, we have "line 1, raised to the second power, gives $aa+2ab+bb=DD$."

ENGLISH: JOHN WALLIS
(1655, 1657, 1685)

195. Wallis used extensively symbols of Oughtred and Harriot, but of course he adopted the exponential notation of Descartes (1637). Wallis was a close student of the history of algebra, as is illustrated

by the exhibition of various notations of powers which Wallis gave in 1657. In Figure 98, on the left, are the names of powers. In the first column of symbols Wallis gives the German symbols as found in *Stifel*, which Wallis says sprang from the letters *r*, *z*, *c*, *s*, the first

letters of the words *res*, *zensus*, *cubus*, *sursolidus*. In the second column are the letters *R*, *Q*, *C*, *S* and their combinations, Wallis remarking that for *R* some write *N*; these were used by Vieta in numerical equations. In the third column are Vieta's symbols in literal algebra, as abbreviated by Oughtred; in the fourth column Harriot's procedure is indicated; in the fifth column is Descartes' exponential notation.

In his *Arithmetica infinitorum*¹ he used the colon as a symbol for aggregation, as $\sqrt{a^2+1}$ for $\sqrt{a^2+1}$, $\sqrt{aD-a^2}$ for $\sqrt{aD-a^2}$; Oughtred's notation for ratio and proportion, $\div\div$ for continued proportion. As the sign for multiplication one finds in this book X and \times , both signs occurring sometimes on one and the same page (for instance, p. 172). In a table (p. 169) he puts \square for a given number: "Verbi gratiâ; si numerus hâc notâ \square designatus supponatur cognitus, reliqui omnes etiam cognoscentur." It is in this book and in his *De*

Resolution of Problemes.		61
By D and T, &c.		
$a = ?$	1	$a + b = D$
$b = ?$	2	$aa + bb = T$
$1 \ominus 3$	3	$aa + bb + 2ab = DD$
$3 - 2$	4	$2ab = DD - T$
$4 * \frac{1}{2}$	5	$4ab = 2DD - 2T$
$3 - 5$	6	$aa + bb - 2ab = 2T - DD$
$6 \omega 2$	7	$a - b = \sqrt{2T - DD}, \&c.$

FIG. 97.—From Brancker's translation of Rahn (1668). The same arrangement of the solution as in 1659, but the omicron-sigma takes the place of the Archimedeian spiral; the ordinal numbers in the outer column are not dotted, while the number in that column which does not refer to steps in the middle column carries a bar, 2. Step 5 means "line 4, multiplied by 2, gives $4ab = 2DD - 2T$."

sectionibus conicis that Wallis first introduces ∞ for infinity. He says (p. 70): "Cum enim primus terminus in serie Primanorum sit 0, primus terminus in serie reciproca erit ∞ vel infinitus: (sicut, in divisione, si diviso sit 0, quotiens erit infinitus)"; on pages 152, 153: "... quippe $\frac{1}{\infty}$ (pars infinite parva) habenda erit pro nihilo," " $\infty \times \frac{1}{\infty} B = B$," "Nam ∞ , $\infty + 1$ $\infty - 1$, perinde sunt"; on page 168: "Quamvis enim $\infty \times 0$ non aliquem determinate numerum designet. . . ." An imitation of Oughtred is Wallis' " $\mathcal{M} : 1 \frac{3}{2}$," which occurs in his famous determination by interpolation of $\frac{4}{\pi}$ as the ratio of two infinite products. At this place he represents our $\frac{4}{\pi}$ by the symbol \square .

¹ *Johannis Wallisii Arithmetica infinitorum* (Oxford, 1655).

He says also (p. 175): "Si igitur ut $\sqrt{3 \times 6}$: significat terminum medium inter 3 et 6 in progressionem Geometricam aequabili 3, 6, 12, etc. (continue multiplicando $3 \times 2 \times 2$ etc.) ita $\mathcal{M}:1|\frac{1}{3}$: significet terminum medium inter 1 et $\frac{1}{3}$ in progressionem Geometricam decrescente 1, $\frac{1}{3}$, $\frac{1}{9}$, etc. (continue multiplicando $1 \times \frac{1}{3} \times \frac{1}{3}$, etc.) erit $\square = \mathcal{M}:1|\frac{1}{3}$: Et propterea circulus est ad quadratum diametri, ut 1 ad $\mathcal{M}:1|\frac{1}{3}$." He uses this symbol again in his *Treatise of Algebra* (1685), pages 296, 362.

FIG. 98.—From John Wallis, *Operum mathematicorum pars prima* (Oxford, 1657), p. 72.

The absence of a special sign for division shows itself in such passages as (p. 135): "Ratio rationis hujus $\frac{1}{2\square}$ ad illam $\frac{1}{2}$, puta $\frac{1}{2}\frac{1}{2\square}\left(\frac{1}{\square}, \text{erit. . . .}\right)$ " He uses Oughtred's clumsy notation for decimal fractions, even though Napier had used the point or comma in 1617. On page 166 Wallis comes close to the modern radical notation; he writes " $\sqrt[6]{R}$ " for $\sqrt[6]{R}$. Yet on that very page he uses the old designation " $\sqrt[6]{qqR}$ " for $\sqrt[6]{R}$.

His notation for continued fractions is shown in the following quotation (p. 191):

“Esto igitur fractio ejusmodi
continue fracta quaelibet, sic
designata,

$$\frac{a}{\alpha} \frac{b}{\beta} \frac{c}{\gamma} \frac{d}{\delta} \frac{e}{\epsilon}, \text{ etc.},”$$

where

$$\frac{a}{\alpha} \frac{b}{\beta} \equiv \frac{a\beta}{\alpha\beta + b}.$$

The suggestion of the use of negative exponents, introduced later by Isaac Newton, is given in the following passage (p. 74): “Ubi autem series directae indices habent 1, 2, 3, etc. ut quae supra seriem Aequalium tot gradibus ascendunt; habebunt hae quidem (illis reciprocae) suos indices contrarios negativos -1, -2, -3, etc. tanquam tot gradibus infra seriem Aequalium descendentes.”

In Wallis' *Mathesis universalis*,¹ the idea of positive and negative integral exponents is brought out in the explanation of the Hindu-Arabic notation. The same principle prevails in the sexagesimal notation, “hoc est, minuta prima, secunda, tertia, etc. ad dextram descendendo,” while ascending on the left are units “quae vocantur Sexagena prima, secunda, tertia, etc. hoc modo.

$\overset{\\}{\\}{\\}{\\} 4\ 9, \overset{\\}{\\}{\\} 3\ 6, \overset{\\}{\\} 2\ 5, \overset{\\}{\\} 1\ 5, \overset{\circ}{\\} 1, \overset{/}{\\} 1\ 5, \overset{''}{\\} 2\ 5, \overset{'''}{\\} 3\ 6, \overset{''''}{\\} 4\ 9.”$

That the consideration of sexagesimal integers of denominations of higher orders was still in vogue is somewhat surprising.

On page 157 he explains both the “scratch method” of dividing one number by another and the method of long division now current, except that, in the latter method, he writes the divisor underneath the dividend. On page 240: “A, M, V $\frac{A}{M}$ ” for arithmetic proportion, i.e., to indicate $M - A = V - M$. On page 292, he introduces a general root d in this manner: “ $\sqrt[d]{R^d} = R$.” Page 335 contains the following interesting combination of symbols:

“Si	$\overbrace{A \cdot B \cdot C} :: \overbrace{a \cdot \beta \cdot \gamma}$	In Modern Symbols
	$\underbrace{\hspace{1.5cm}} :: \underbrace{\hspace{1.5cm}}$	If $A:B = a:\beta$,
Erit	$A \cdot C :: a \cdot \gamma.”$	and $B:C = \beta:\gamma$,
		then $A:C = a:\gamma$.

196. In the *Treatise of Algebra*² (p. 46), Wallis uses the decimal point, placed at the lower terminus of the letters, thus: 3.14159,

¹ *Johannis Wallisii Mathesis universalis: sive, Arithmetikum opus integrum* (Oxford, 1657), p. 65-68.

² *Op. cit.* (London, 1685).

26535. . . . , but on page 232 he uses the comma, "12,756," "3936." On page 67, describing Oughtred's *Clavis mathematicae*, Wallis says: "He doth also (to very great advantage) make use of several Ligatures, or Compendious Notes, to signify the *Summs*, *Differences*, and *Rectangles* of several Quantities. As for instance, Of two quantities *A* (the Greater, and *E* (the Lesser,) the Sum he calls *Z*, the Difference *X*, the Rectangle *Æ*. . . ." On page 109 Wallis summarizes various practices: "The Root of such Binomial or Residual is called a Root universal; and thus marked \sqrt{u} , (Root universal,) or \sqrt{b} , (Root of a Binomial,) or \sqrt{r} , (Root of a Residual,) or drawing a Line over the whole Compound quantity; or including it (as Oughtred used to do) within two colons; or by some other distinction, whereby it may appear, that the note of Radicality respects, not only the single quantity next adjoining, but the whole Aggregate. As $\sqrt{b} : 2 + \sqrt{3} \cdot \sqrt{r} : 2 - \sqrt{3} \cdot \sqrt{u} : 2 \pm \sqrt{3} \cdot \sqrt{2 \pm \sqrt{3}} \cdot \sqrt{r} : 2 \pm \sqrt{3}$; etc."

On page 227 Wallis uses Rahn's sign \div for division; along with the colon as the sign of aggregation it gives rise to oddities in notation like the following: " $ll - 2laa + a^4 : \div bb$."

On page 260, in a geometric problem, he writes " $\square AE$ " for the square of the line *AE*; he uses \mp for the absolute value of the difference.

On page 317 his notation for infinite products and infinite series is as follows:

$$"1 \times 1\frac{1}{2} \times 1\frac{1}{4} \times 1\frac{1}{8} \times 1\frac{1}{16} \times 1\frac{1}{32} \times 1\frac{1}{64} \times \text{etc.}"$$

$$"1 + \frac{1}{8}A + \frac{1}{4}B + \frac{1}{8}C + \frac{1}{16}D + \frac{1}{32}E + \frac{1}{64}F + \text{etc.};"$$

on page 322:

$$"\sqrt{r} : 2 - \sqrt{r} : 2 + \sqrt{r} : 2 + \sqrt{2}" \text{ for } \sqrt{2 - \sqrt{2 + \sqrt{2 + \sqrt{2}}}}$$

On page 332 he uses fractional exponents (Newton having introduced the modern notation for negative and fractional exponents in 1676) as follows:

$$"\sqrt[5]{c^5 + c^4x - x^5} : \quad \text{or} \quad \overline{c^5 + c^4x - x^5}^{\frac{1}{5}}."$$

The difficulties experienced by the typesetter in printing fractional exponents are exhibited on page 346, where we find, for example, " $d^{\frac{1}{2}} x^{\frac{1}{2}}$ " for $d^{\frac{1}{2}}x^{\frac{1}{2}}$. On page 123, the factoring of 5940 is shown as follows:

$$"(11)5)3)3)3)2)2) \ 5940 \ (2970(1485(495(165(55(11(1."$$

In a letter to John Collins, Wallis expresses himself on the sign of multiplication: "In printing my things, I had rather you make use of Mr. Oughtred's note of multiplication, \times , than that of $*$; the other being the more simple. And if it be thought apt to be mistaken for X , it may [be] helped by making the upper and lower angles more obtuse \bowtie ." ¹ "I do not understand why the sign of multiplication \times should more trouble the convenient placing of the fractions than the other signs $+ - = > ::$." ²

Wallis, in presenting the history of algebra, stressed the work of Harriot and Oughtred. John Collins took some exception to Wallis' attitude, as is shown in the following illuminating letter. Collins says: ³ "You do not like those words of Vieta in his theorems, *ex adjunctione plano solidi, plus quadrato quadrati*, etc., and think Mr. Oughtred the first that abridged those expressions by symbols; but I dissent, and tell you 'twas done before by Cataldus, Geysius, and Camillus Gloriosus, ⁴ who in his first decade of exercises, (not the first tract,) printed at Naples in 1627, which was four years before the first edition of the *Clavis*, proposeth this equation just as I here give it you, viz., $1ccc + 16qcc + 41qqc - 2304cc - 18364qc - 133000qq - 54505c + 3728q + 8064N$ aequatur 4608, finds N or a root of it to be 24, and composeth the whole out of it for proof, just in Mr. Oughtred's symbols and method. Cataldus on Vieta came out fifteen years before, and I cannot quote that, as not having it by me. . . . And as for Mr. Oughtred's method of symbols, this I say to it; it may be proper for you as a commentator to follow it, but divers I know, men of inferior rank that have good skill in algebra, that neither use nor approve it. . . . Is not A^5 sooner wrote than Aqc ? Let A be 2, the cube of 2 is 8, which squared is 64: one of the questions between Magnet Grisio and Gloriosus is whether $64 = A_{cc}$ or A_{qc} . The Cartesian method tells you it is A^6 , and decides the doubt."

EXTRACT FROM ACTA ERUDITORUM⁵

197. "Monendum denique, nos in posterum in his Actis usuros esse Signis *Leibnitianis*, ubi cum *Algebraicis* res nobis fuerit, ne typothetis

⁵ Taken from *Acta eruditorum* (Leipzig, 1708), p. 271.

taedia & molestias gratis creemus, utque ambiguitates evitemus. Loco igitur lineolae characteribus supraducendae parentheses adhibebimus, immo in multiplicatione simplex comma, ex. gr. loco $Vaa+bb$ scribemus $V(aa+bb)$ & pro $\overline{aa+bb} \times c$ ponemus $aa+bb, c$. Divisionem designabimus per duo puncta, nisi peculiaris quaedam circumstantia morem vulgarem adhiberi suaserit. Ita nobis erit $a:b = \frac{a}{b}$. Et hinc peculiaribus signis ad denotandam proportionem nobis non erit opus. Si enim fuerit ut a ad b ita c ad d , erit $a:b = c:d$. Quod potentias attinet, $\overline{aa+bb}^m$ designabimus per $(aa+bb)^m$: unde & $\sqrt[m]{Vaa+bb}$ erit $= (aa+bb)^{1:m}$ & $\sqrt[n]{Vaa+bb^n} = (aa+bb)^{n:m}$. Nulli vero dubitamus fore, ut Geometrae omnes Acta haec legentes Signorum Leibnitianorum praestantiam animadvertant, & nobiscum in eadem consentiant."

The translation is as follows: "We hereby issue the reminder that in the future we shall use in these *Acta* the Leibnizian signs, where, when algebraic matters concern us, we do not choose the typographically troublesome and unnecessarily repugnant, and that we avoid ambiguity. Hence we shall prefer the parenthesis to the characters consisting of lines drawn above, and in multiplication by all means simply the comma; for example, in place of $\sqrt{aa+bb}$ we write $\sqrt[1]{(aa+bb)}$ and for $\overline{aa+bb} \times c$ we take $aa+bb, c$. Division we mark with two dots, unless indeed some peculiar circumstance directs adherence to the usual practice. Accordingly, we have $a:b = \frac{a}{b}$. And it is not necessary to denote proportion by any special sign. For, if a is to b as c is to d , we have $a:b = c:d$. As regards powers, $\overline{aa+bb}^m$, we designate them by $(aa+bb)^m$; whence also $\sqrt[m]{Vaa+bb}$ becomes $= (aa+bb)^{1:m}$ and $\sqrt[n]{Vaa+bb^n} = (aa+bb)^{n:m}$. We do not doubt that all geometers who read the *Acta* will recognize the excellence of the Leibnizian symbols and will agree with us in this matter."

EXTRACT FROM MISCELLANEA BEROLINENSIA¹

198. "*Monitum De Characteribus Algebraicis*.—Quoniam variant Geometrae in characterum usu, nova praesertim Analysis inventa; quae res legentibus non admodum provecitis obscuritatem parit; ideo è re visum est exponere, quomodo Characteres adhibeantur Leibnitiano more, quem in his Miscellaneis secuturi sumus. *Litterae*

¹ Taken from *Miscellanea Berolinensia* (1710), p. 155. Article due to G. W. Leibniz.

minusculae a, b, x, y solent significare magnitudines, vel quod idem est, numeros indeterminatos: Majusculae verò, ut A, B, X, Y puncta figurarum; ita ab significat factum ex a in b , sed AB rectam à puncto A ad punctum B ductam. Huic tamen observationi adeo alligati non sumus, ut non aliquando minusculas pro punctis, majusculas pro numeris vel magnitudinibus usurpemus, quod facile apparebit ex modo adhibendi. Solent etiam literae priores, ut a, b , pro quantitativis cognitis vel saltem determinatis adhiberi, sed posteriores, ut x, y , pro incognitis vel saltem pro variantibus.

“Interdum pro literis adhibentur Numeri, sed qui idem significant quod literae, utiliter tamen usurpantur relationis exprimendae gratia. Exempli causa: Sint binae aequationes generales secundi gradus pro incognita, x ; eas sic exprimere licebit: $10xx \rightarrow 11x \rightarrow 12 = 0$ & $20xx \rightarrow 21x \rightarrow 22 = 0$ ita in progressu calculi ex ipsa notatione apparet quantitatis cujusque relatio; nempe 21 (ex. gr.) per notam dextram, quae est 1 agnoscitur esse coëfficiens ipsius x simplicis, at per notam sinistram 2 agnoscitur esse ex. aeq. secunda: sed et servatur lex quaedam homogeneorum. Et ope harum duarum aequationum tollendo x , prodit aequatio, in qua similiter se habere oportet 10, 11, 12 et 12, 11, 10; item 20, 21, 22 et 22, 21, 20; et denique 10, 11, 12 se habent ut. 20, 21, 22. id est si pro 10, 11, 12 substituas 20, 21, 22 et vice versa manet eadem aequatio; idemque est in caeteris. Tales numeri tractantur ut literae, veri autem numeri, discriminis causa, parenthesis includuntur vel aliter discernuntur. Ita in tali sensu 11.20. significat numeros indefinitos 11 et 20 in se invicem ductos, non vero significat 220 quasi essent Numeri veri. Sed hic usus ordinarius non est, rariusque adhibetur.

“*Signa, Additionis* nimirum et *Subtractionis*, sunt \rightarrow plus, $-$ minus, \rightarrow plus vel minus, $\overline{-}$ priori oppositum minus vel plus. At (\rightarrow) vel $(\overline{-})$ est nota ambiguitatis signorum, independens à priori; et $((\rightarrow))$ vel $((\overline{-}))$ alia independens ab utraque; Differt autem *Signum ambiguum a Differentia* quantitatum, quae etsi aliquando incerta, non tamen ambigua est. . . . Sed differentia inter a et b , significat $a - b$, si a sit majus, et $b - a$ si b sit majus, quod etiam appellari potest moles ipsius $a - b$, intelligendo (exempli causa) ipsius $\rightarrow 2$ et ipsius $- 2$ molem esse eandem, nempe $\rightarrow 2$; ita si $a - b$ vocemus c utique *mol. c*, seu moles ipsius c erit $\rightarrow 2$, quae est quantitas affirmativa sive c sit affirmativa sive negativa, id est, sive sit c idem quod $\rightarrow 2$, sive c sit idem quod $- 2$. Et quantitates duae diversae eandem molem habentes semper habent idem quadratum.

"*Multiplicationem* plerumque significare contenti sumus per nudam appositionem: sic ab significat a multiplicari per b , Numeros multiplicantes solemus praefigere, sic $3a$ significat triplum ipsius a interdum tamen punctum vel comma interponimus inter multiplicans et multiplicandum, velut cum $3, 2$ significat 3 multiplicari per 2 , quod facit 6 , si 3 et 2 sunt numeri veri; et AB, CD significat rectam AB duci in rectam CD , atque inde fieri rectangulum. Sed et commata interdum hoc loco adhibemus utiliter, velut $a, b \cdot \text{---} c$, vel $AB, CD \text{---} EF$, id est, a duci in $b \text{---} c$, vel AB in $CD \text{---} EF$; sed de his mox, ubi de vinculis. Porro propria Nota Multiplicationis non solet esse necessaria, cum plerumque appositio, qualem diximus, sufficiat. Si tamen utilis aliquando sit, adhibebitur potius \cap quam \times , quia hoc ambiguitatem parit, et ita $AB \cap CD$ significat AB duci in CD .

"*Diviso* significatur interdum more vulgari per subscriptionem diuisoris sub ipso dividendo, intercedente linea, ita a dividi per b , significatur vulgo per $\frac{a}{b}$; plerumque tamen hoc evitare praestat, efficereque, ut in eadem linea permaneat, quod sit interpositis duobus punctis; ita ut $a:b$ significat a dividi per b . Quod si $a:b$ rursus dividi debeat per c , poterimus scribere $a:b, :c$, vel $(a:b):c$. Etsi enim res hoc casu (sane simplici) facile aliter exprimi posset, fit enim $a:(bc)$ vel $a:bc$ non tamen semper divisio actu ipse facienda est, sed saepe tantum indicanda, et tunc praestat operationis dilatae processum per commata vel parentheses indicari. . . . Et exponens interdum lineolis includitur hac modo $\boxed{3}(AB \text{---} BC)$ quo significatur cubus rectae $AB \text{---} BC$ a^{e+n} et utiliter interdum lineola subducitur, ne literae exponentiales aliis confundantur; posset etiam scribi $\boxed{e+n} a$

" . . . ita $\sqrt[3]{(a^3)}$ vel $\sqrt{\boxed{3}}(a^3)$ rursus est a , . . . sed $\sqrt[3]{2}$ vel $\sqrt{\boxed{3}}2$ significat radicem cubicam ex eodem numero, et $\sqrt[3]{2}$ vel $\sqrt{\boxed{e}}2$ significat, radicem indeterminati gradus e ex 2 extrahendam. . . .

"Pro vinculis vulgo solent adhiberi ductus linearum; sed quia lineis una super alia ductis, saepe nimium spatii occupatur, aliasque ob causas commodius plerumque adhibentur commata et parentheses. Sic $a, b \cdot \text{---} c$ idem est quod $a, b \text{---} c$ vel $a(b \text{---} c)$; et $a \cdot \text{---} b, c \text{---} d$ idem quod $a \text{---} b, c \text{---} d$ vel $(a \text{---} b)(c \text{---} d)$, id est, $\text{---} a \text{---} b$ multiplicatum per $c \text{---} d$. Et similiter vincula in vinculis exhibentur. Ita $a, \overline{bc \text{---} ef \text{---} g}$ etiam sic exprimitur, $a(bc \text{---} e(f \text{---} g))$ Et $a, \overline{bc \text{---} ef \text{---} g \text{---} hlm}$, n potest etiam

sic exprimi: $\cdot\frac{1}{2}\cdot (a(bc\cdot\frac{1}{2}\cdot e(f+g)) + hlm)n$. Quod de vinculis multiplicationis, idem intelligi potest *de vinculis divisionis*, exempli gratia

$$\frac{\frac{a}{\frac{b}{c} \cdot \frac{1}{2} \cdot \frac{e}{f \cdot \frac{1}{2} \cdot \frac{g}{m}}}}{\cdot \frac{1}{2} \cdot \frac{h}{l}} \quad \text{sic scribetur in una linea}$$

$$(a : ((b : c) \cdot \frac{1}{2} \cdot (e : (f \cdot \frac{1}{2} \cdot g))) \cdot \frac{1}{2} \cdot h : (l : m)) : n$$

nihilque in his difficultatis, modo teneamus, quicquid parenthesin aliquam implet pro una quantitate haberi, Idemque igitur locum habet in vinculis extractionis radicalis.

Sic $\sqrt[4]{a \cdot \frac{1}{2} \cdot \sqrt{e, f \cdot \frac{1}{2} \cdot g}}$ idem est quod $\sqrt[4]{(a \cdot \frac{1}{2} \cdot \sqrt{(e(f \cdot \frac{1}{2} \cdot g)))})}$ vel $\sqrt[4]{(a \cdot \frac{1}{2} \cdot \sqrt{(e, f \cdot \frac{1}{2} \cdot g)})}$.

$$\text{Et pro } \frac{\sqrt{aa \cdot \frac{1}{2} \cdot b} \sqrt{cc \cdot \frac{1}{2} \cdot dd}}{c \cdot \frac{1}{2} \cdot \sqrt{f} \sqrt{gg \cdot \frac{1}{2} \cdot hh} \cdot \frac{1}{2} \cdot kk}$$

scribi poterit $\sqrt{(aa \cdot \frac{1}{2} \cdot b} \sqrt{(cc \cdot \frac{1}{2} \cdot dd)}) :$,
 $c \cdot \frac{1}{2} \cdot \sqrt{(f} \sqrt{(gg \cdot \frac{1}{2} \cdot hh)} \cdot \frac{1}{2} \cdot kk) \dots$

itaque $a=b$ significat, a , esse equale ipsi b , et $a \equiv b$ significat a esse majus quam b , et $a \equiv b$ significat a esse minus quam b .

"Sed et *proportionalitas* vel analogia de quantitativis enunciat, id est, rationis identitas, quam possumus in Calculo exprimere per notam aequalitatis, ut non sit opus peculiaribus notis. Itaque a esse ad b , sic ut l ad m , sic exprimere poterimus $a:b=l:m$, id est $\frac{a}{b} = \frac{l}{m}$.

Nota continue proportionalium erit $\div\div$, ita ut $\div\div a.b.c$ etc. sint continuè proportionales. Interdum nota *Similitudinis* prodest, quae est ∞ , item nota similitudinis aequalitatis simul, seu nota *congruitatis* \cong , Sic $DEF \infty PQR$ significabit Triangula haec duo esse similia; at $DEF \cong PQR$ significabit congruere inter se. Huic si tria inter se habeant eandem rationem quam tria alia inter se, poterimus hoc exprimere nota similitudinis, ut $a; b; \infty l; m; n$ quod significat esse a ad b , ut l ad m , et a ad c ut l ad n , et b ad c ut m ad n"

The translation is as follows:

"*Recommendations on algebraic characters*.—Since geometers differ in the use of characters, especially those of the newly invented analysis, a situation which perplexes those followers who as yet are not very far advanced, it seems proper to explain the manner of using the characters in the Leibnizian procedure, which we have adopted in the

Miscellanies. The small letters a, b, x, y , signify magnitudes, or what is the same thing, indeterminate numbers. The capitals on the other hand, as A, B, X, Y , stand for points of figures. Thus ab signifies the result of a times b , but AB signifies the right line drawn from the point A to the point B . We are, however, not bound to this convention, for not infrequently we shall employ small letters for points, capitals for numbers or magnitudes, as will be easily evident from the mode of statement. It is customary, however, to employ the first letters a, b , for known or fixed quantities, and the last letters x, y , for the unknowns or variables.

"Sometimes numbers are introduced instead of letters, but they signify the same as letters; they are convenient for the expression of relations. For example, let there be two general equations of the second degree having the unknown x . It is allowable to express them thus: $10xx+11x+12=0$ and $20xx+21x+22=0$. Then, in the progress of the calculation the relation of any quantity appears from the notation itself; thus, for example, in 21 the right digit which is 1 is recognized as the coefficient of x , and the left digit 2 is recognized as belonging to the second equation; but also a certain law of homogeneity is obeyed. And eliminating x by means of these two equations, an equation is obtained in which one has similarity in 10, 11, 12 and 12, 11, 10; also in 20, 21, 22 and 22, 21, 20; and lastly in 10, 11, 12 and 20, 21, 22. That is, if for 10, 11, 12, you substitute 20, 21, 22 and vice versa, there remains the same equation, and so on. Such numbers are treated as if letters. But for the sake of distinction, they are included in parentheses or otherwise marked. Accordingly, 11·20. signifies the indefinite numbers 11 and 20 multiplied one into the other; it does not signify 220 as it would if they were really numbers. But this usage is uncommon and is rarely applied.

"The *signs of addition* and subtraction are commonly $+$ plus, $-$ minus, \pm plus or minus, \mp the opposite to the preceding, minus or plus. Moreover (\pm) or (\mp) is the mark of ambiguity of signs that are independent at the start; and $((\pm))$ or $((\mp))$ are other signs independent of both the preceding. Now the symbol of ambiguity differs from the difference of quantities which, although sometimes undetermined, is not ambiguous. . . . But $a-b$ signifies the difference between a and b when a is the greater, $b-a$ when b is the greater, and this absolute value (moles) may however be called itself $a-b$, by understanding that the absolute value of $+2$ and -2 , for example, is the same, namely, $+2$. Accordingly, if $a-b$ is called c , then *mol. c* or the absolute value of c is $+2$, which is an affirmative quantity whether

c itself is positive or negative; i.e., either c is the same as $+2$, or c is the same as -2 . Two different quantities having the same absolute value have always the same square.

"*Multiplication* we are commonly content to indicate by simple apposition: thus, ab signifies a multiplied by b . The multiplier we are accustomed to place in front; thus $3a$ means the triple of a itself. Sometimes, however, we insert a point or a comma between multiplier and multiplicand; thus, for example, $3,2$ signifies that 3 is multiplied by 2, which makes 6, when 3 and 2 are really numbers; and AB,CD signifies the right line AB multiplied into the right line CD , producing a rectangle. But we also apply the comma advantageously in such a case, for example,¹ as $a,b+c$, or $AB,CD+EF$; i.e., a multiplied into $b+c$, or AB into $CD+EF$; we speak about this soon, under vinculum. Formerly no sign of multiplication was considered necessary for, as stated above, commonly mere apposition sufficed. If, however, at any time a sign seems desirable use \cap rather than \bowtie , because the latter leads to ambiguity; accordingly, $AB\cap CD$ signifies AB times CD .

"*Division* is commonly marked by writing the divisor beneath its dividend, with a line of separation between them. Thus a divided by b is ordinarily indicated by $\frac{a}{b}$; often, however, it is preferable to avoid this notation and to arrange the signs so that they are brought into one and the same line; this may be done by the interposition of two points; thus $a:b$ signifies a divided by b . If $a:b$ in turn is to be divided by c , we may write $a:b, :c$, or $(a:b):c$. However, this should be expressed more simply in another way, namely, $a:(bc)$ or $a:bc$, for the division cannot always be actually carried out, but can be only indicated, and then it becomes necessary to mark the delayed process of the operation by commas or parentheses. . . . Exponents are frequently inclosed by lines in this manner $\boxed{3}$ ($AB+BC$), which means the cube of the line $AB+BC$. . . ; the exponents of a^{l+n} may also be advantageously written between the lines, so that the literal exponents will not be confounded with other letters; thus it may be written $\boxed{l+n} a$ From $\sqrt[3]{(a^3)}$ or $\sqrt{\boxed{3}}(a^3)$ arises a . . . ; but $\sqrt[3]{2}$ or $\sqrt{\boxed{3}} 2$ means the cube root of the same number, and $\sqrt[3]{2}$ or $\sqrt{\boxed{e}} 2$ signifies the extraction of a root of the indeterminate order e

"For aggregation it is customary to resort to the drawing of

¹ A similar use of the comma to separate factors and at the same time express aggregation occurs earlier in Hérigone (see § 189).

lines, but because lines drawn one above others often occupy too much space, and for other reasons, it is often more convenient to introduce commas and parentheses. Thus $a, \overline{b+c}$ is the same as $a, b+c$ or $a(b+c)$; and $\overline{a+b}, \overline{c+d}$ is the same as $a+b, c+d$, or $(a+b)(c+d)$, i.e., $+a+b$ multiplied by $c+d$. And, similarly, vinculums are placed under vinculums. For example, $a, \overline{bc+ef+g}$ is expressed also thus, $a(\overline{bc+e(f+g)})$, and $a, \overline{bc+ef+g+hlm}, n$ may be written also $+(a(\overline{bc+e(f+g)})+hlm)n$. What relates to vinculums in multiplication applies to vinculums in division. For example,

$$\frac{\frac{a}{b+\frac{e}{c+f+g}}+\frac{h}{m}}{n} \quad \text{may be written in one line thus:}$$

$$(a: ((b:c)+(e:, f+g))+h:(l:m)):n ,$$

and there is no difficulty in this, as long as we observe that whatever fills up a given parenthesis be taken as one quantity. . . . The same is true of vinculums in the extraction of roots. Thus $\sqrt{a^4+\sqrt{e, f+g}}$ is the same as $\sqrt{(a^4+\sqrt{e(f+g)})}$ or $\sqrt{(a^4+\sqrt{(e, f+g)})}$. And

for $\sqrt{\frac{aa+b\sqrt{cc+dd}}{e+\sqrt{f}\sqrt{gg+hh+kk}}}$ one may write $\sqrt{(aa+b\sqrt{(cc+dd)}):, e+}$

$\sqrt{(f\sqrt{(gg+hh)+kk})}$. Again $a=b$ signifies that a is equal to b , and $a>b$ signifies that a is greater than b , and $a<b$ that a is less than b . Also proportionality or analogia of quantities, i.e., the identity of ratio, may be represented; we may express it in the calculus by the sign of equality, for there is no need of a special sign. Thus, we may indicate that a is to b as l is to m by $a:b=l:m$, i.e., $\frac{a}{b}=\frac{l}{m}$. The sign for continued proportion is $\div\div$, so that $\div\div a, b, c$, and d are continued proportionals.

"There is adopted a sign for similitude; it is ∞ ; also a sign for both similitude and equality, or a sign of congruence, \cong accordingly, $DEF \infty PQR$ signifies that the two triangles are similar; but $DEF \cong PRQ$ marks their congruence. Hence, if three quantities have to one another the same ratio that three others have to one another, we may mark this by a sign of similitude, as $a; b; c \infty l; m; n$ means that a is to b as l is to m , and a is to c as l is to n , and b is to c as m is to n"

In the second edition of the *Miscellanea Berolinensia*, of the year

1749, the typographical work is less faulty than in the first edition of 1710; some slight errors are corrected, but otherwise no alterations are made, except that Harriot's signs for "greater than" and "less than" are adopted in 1749 in place of the two horizontal lines of unequal length and thickness, given in 1710, as shown above.

199. *Conclusions*.—In a letter to Collins, John Wallis refers to a change in algebraic notation that occurred in England during his lifetime: "It is true, that as in other things so in mathematics, fashions will daily alter, and that which Mr. Oughtred designed by great letters may be now by others be designed by small; but a mathematician will, with the same ease and advantage, understand Ac , and a^3 or aaa ."¹ This particular diversity is only a trifle as compared with what is shown in a general survey of algebra in Europe during the fifteenth, sixteenth, and seventeenth centuries. It is discouraging to behold the extreme slowness of the process of unification.

In the latter part of the fifteenth century \tilde{p} and \tilde{m} became symbols for "plus" and "minus" in France (§ 131) and Italy (§ 134). In Germany the Greek cross and the dash were introduced (§ 146). The two rival notations competed against each other on European territory for many years. The \tilde{p} and \tilde{m} never acquired a foothold in Germany. The German $+$ and $-$ gradually penetrated different parts of Europe. It is found in Scheubel's *Algebra* (§ 158), in Recorde's *Whetstone of Witte*, and in the *Algebra* of Clavius. In Spain the German signs occur in a book of 1552 (§ 204), only to be superseded by the \tilde{p} and \tilde{m} in later algebras of the sixteenth century. The struggle lasted about one hundred and thirty years, when the German signs won out everywhere except in Spain. Organized effort, in a few years, could have ended this more than a century competition.

If one takes a cross-section of the notations for radical expressions as they existed in algebra at the close of the sixteenth century, one finds four fundamental symbols for indicating roots, the letters R and l , the radical sign $\sqrt{\quad}$ proper and the fractional exponent. The letters R and l were sometimes used as capitals and sometimes as small letters (§§ 135, 318–22). The student had to watch his step, for at times these letters were used to mark, not roots, but the unknown quantity x and, perhaps, also its powers (§ 136). When R stood for "root," it became necessary to show whether the root of one term or of several terms was meant. There sprang up at least seven different symbols for the aggregation of terms affected by the R , namely, one of Chuquet (§ 130), one of Pacioli (§ 135), two of Cardan (§ 141), the round paren-

¹ See Rigaud, *op. cit.*, Vol. II, p. 475.

thesis of Tartaglia (§ 351), the upright and inverted letter L of Bombelli (§ 144), and the r bin. and r trinomia of A. V. Roomen (§ 343). There were at least five ways of marking the orders of the root, those of Chuquet (§ 130), De la Roche (§ 132), Pacioli (§ 135), Ghaligai (§ 139), and Cardan (Fig. 46). With A. M. Visconti¹ the signs $R.ce$ cu. meant the "sixth root"; he used the multiplicative principle, while Pacioli used the additive one in the notation of radicals. Thus the letter R carried with it at least fifteen varieties of usage. In connection with the letter l , signifying *latus* or "root," there were at least four ways of designating the orders of the roots and the aggregation of terms affected (§§ 291, 322). A unique line symbolism for roots of different orders occurs in the manuscripts of John Napier (§ 323).

The radical signs for cube and fourth root had quite different shapes as used by Rudolff (§§ 148, 326) and Stifel (§ 153). Though clumsier than Stifel's, the signs of Rudolff retained their place in some books for over a century (§ 328). To designate the order of the roots, Stifel placed immediately after the radical sign the German abbreviations of the words *zensus*, *cubus*, *zensizensus*, *sursolidus*, etc. Stevin (§ 163) made the important innovation of numeral indices. He placed them within a circle. Thus he marked cube root by a radical sign followed by the numeral 3 coraled in a circle. To mark the root of an aggregation of terms, Rudolff (§§ 148, 348) introduced the dot placed after the radical sign; Stifel sometimes used two dots, one before the expression, the other after. Stevin (§§ 163, 343) and Digges (§§ 334, 343) had still different designations. Thus the radical sign carried with it seven somewhat different styles of representation. Stevin suggested also the possibility of fractional exponents (§ 163), the fraction being placed inside a circle and before the radicand.

Altogether there were at the close of the sixteenth century twenty-five or more varieties of symbols for the calculus of radicals with which the student had to be familiar, if he desired to survey the publications of his time.

Lambert Lincoln Jackson makes the following historical observations: "For a hundred years after the first printed arithmetic many writers began their works with the line-reckoning and the Roman numerals, and followed these by the Hindu arithmetic. The teaching of numeration was a formidable task, since the new notation was so unfamiliar to people generally."² In another place (p. 205) Jackson

¹ "Abbreviationes," *Practica numerorum, et mensurarum* (Brescia, 1581).

² *The Educational Significance of Sixteenth Century Arithmetic* (New York, 1906), p. 37, 38.

states: "Any phase of the growth of mathematical notation is an interesting study, but the chief educational lesson to be derived is that notation always grows too slowly. Older and inferior forms possess remarkable longevity, and the newer and superior forms appear feeble and backward. We have noted the state of transition in the sixteenth century from the Roman to the Hindu system of characters, the introduction of the symbols of operation, $+$, $-$, and the slow growth toward the decimal notation. The moral which this points for twentieth-century teachers is that they should not encourage history to repeat itself, but should assist in hastening new improvements."

The historian Tropfke expresses himself as follows: "How often has the question been put, what further achievements the patriarchs of Greek mathematics would have recorded, had they been in possession of our notation of numbers and symbols! Nothing stirs the historian as much as the contemplation of the gradual development of devices which the human mind has thought out, that he might approach the truth, enthroned in inaccessible sublimity and in its fullness always hidden from earth. Slowly, only very slowly, have these devices become what they are to man today. Numberless strokes of the file were necessary, many a chink, appearing suddenly, had to be mended, before the mathematician had at hand the sharp tool with which he could make a successful attack upon the problems confronting him. The history of algebraic language and writing presents no uniform picture. An assemblage of conscious and unconscious innovations, it too stands subject to the great world-law regulating living things, the principle of selection. Practical innovations make themselves felt, unsuitable ones sink into oblivion after a time. The force of habit is the greatest opponent of progress. How obstinate was the struggle, before the decimal division met with acceptance, before the proportional device was displaced by the equation, before the Indian numerals, the literal coefficients of Vieta, could initiate a world mathematics."¹

Another phase is touched by Treutlein: "Nowhere more than in mathematics is intellectual content so intimately associated with the form in which it is presented, so that an improvement in the latter may well result in an improvement of the former. Particularly in arithmetic, a generalization and deepening of concept became possible only after the form of presentation had been altered. The history of our science supplies many examples in proof of this. If the Greeks had been in possession of our numeral notation, would their

¹ Tropfke, *Geschichte der Elementar-Mathematik*, Vol. II (Leipzig, 1921), p. 4, 5.

mathematics not present a different appearance? Would the binomial theorem have been possible without the generalized notation of powers? Indeed could the mathematics of the last three hundred years have assumed its degree of generality without Vietà's pervasive change of notation, without his introduction of general numbers? These instances, to which others from the history of modern mathematics could be added, show clearly the most intimate relation between substance and form."¹

B. SPECIAL SURVEY OF THE USE OF NOTATIONS

SIGNS FOR ADDITION AND SUBTRACTION

200. *Early symbols*.—According to Hilprecht,² the early Babylonians had an ideogram, which he transliterates *LAL*, to signify "minus." In the hieratic papyrus of Ahmes and, more clearly in the hieroglyphic translation of it, a pair of legs walking forward is the sign of addition; away, the sign of subtraction.³ In another Egyptian papyrus kept in the Museum of Fine Arts in Moscow,⁴ a pair of legs walking forward has a different significance; there it means to square a number.

Figure 99, translated, is as follows (reading the figure from right to left):

" $\frac{2}{3}$ added and $\frac{1}{3}$ [of this sum] taken away, 10 remains.
Make $\frac{1}{10}$ of this 10: the result is 1, the remainder 9.
 $\frac{2}{3}$ of it, namely, 6, added to it; the total is 15. $\frac{1}{3}$ of it is 5.
When 5 is taken away, the remainder is 10."

In the writing of unit fractions, juxtaposition meant addition, the unit fraction of greatest value being written first and the others in descending order of magnitude.

While in Diophantus addition was expressed merely by juxtaposition (§ 102), a sporadic use of a slanting line / for addition, also a semi-elliptical curve 2 for subtraction, and a combination of the two

⁴ Peet, *op. cit.*, p. 20, 135: *Ancient Egypt* (1917), p. 101.

\cap for the total result has been detected in Greek papyri.¹ Diophantus' sign for subtraction is well known (§ 103). The Hindus had no mark for addition (§ 106) except that, in the Bakhshali *Arithmetic*, *yu* is used for this purpose (§ 109). The Hindus distinguished negative quantities by a dot (§§ 106, 108), but the Bakhshali *Arithmetic* uses the sign $+$ for subtraction (§ 109). The Arab al-Qalasâdî in the fifteenth century indicated addition by juxtaposition and had a special sign for subtraction (§ 124). The Frenchman Chuquet (1484), the Italian Pacioli (1494), and the sixteenth-century mathematicians in Italy used \tilde{p} or p : for plus and \tilde{m} or m : for "minus" (§§ 129, 134).

FIG. 99.—From the hieroglyphic translation of the Ahmes papyrus, Problem 28, showing a pair of legs walking forward, to indicate addition, and legs walking away, to indicate subtraction. (Taken from T. E. Peet, *The Rhind Mathematical Papyrus*, Plate J, No. 28.)

201. *Origin and meanings of the signs $+$ and $-$.*—The modern algebraic signs $+$ and $-$ came into use in Germany during the last twenty years of the fifteenth century. They are first found in manuscripts. In the Dresden Library there is a volume of manuscripts, C. 80. One of these manuscripts is an algebra in German, written in the year 1481,² in which the minus sign makes its first appearance in

¹ H. Brugsch, *Numerorum apud veteres Aegyptios demoticorum doctrina. Ex papyris* (Berlin, 1849), p. 31; see also G. Friedlein, *Zahlzeichen und das elementare Rechnen* (Erlangen, 1869), p. 19 and Plate I.

Jahrhundert*, *Zwickauer Gymnasialprogramm von 1887*, p. 11–30 (quoted by Cantor, *op. cit.*, Vol. II [2d ed., 1900], p. 243, and by Tropicke, *op. cit.*, Vol. II [2d ed., 1921], p. 13).

algebra (Fig. 100); it is called *minnes*. Sometimes the $-$ is placed after the term affected. In one case -4 is designated "4 das ist $-$." Addition is expressed by the word *vnd*.

In a Latin manuscript in the same collection of manuscripts, C. 80, in the Dresden Library, appear both symbols $+$ and $-$ as signs of operation (Fig. 101), but in some rare cases the $+$ takes the place of *et* where the word does not mean addition but the general "and."¹ Repeatedly, however, is the word *et* used for addition.

It is of no little interest that J. Widman, who first used the $+$ and $-$ in print, studied these two manuscripts in the manuscript volume C. 80 of the Dresden Library and, in fact, annotated them. One of his marginal notes is shown in Figure 102. Widman lectured at the University of Leipzig, and a manuscript of notes taken in 1486 by a pupil is preserved in the Leipzig Library (Codex Lips. 1470).² These notes show a marked resemblance to the two Dresden manuscripts.

The view that our $+$ sign descended from one of the florescent forms for *et* in Latin manuscripts finds further support from works on

+. The downward stroke is not quite at right angles to the horizontal stroke, thus \nmid .

Concerning the origin of the minus sign ($-$), we limit ourselves to the quotation of a recent summary of different hypotheses: "One knows nothing certain of the origin of the sign $-$; perhaps it is a simple bar used by merchants to separate the indication of the tare, for a long time called *minus*, from that of the total weight of merchandise; according to L. Rodet (*Actes*

Zusatz von WIDMANN.

5. Dresd. C. 80, fol. 349'

(um 1486)

$$\begin{array}{r} 360 \text{ 2e} \\ 144 \phi - \sigma \text{ 2e} \end{array} \qquad \begin{array}{r} 360 x \\ 144 - 6x \end{array}$$

FIG. 102.—Widman's marginal note to MS C. 80, Dresden Library. (Taken from Tropfke.)

Soc. philol. Alençon, Vol. VIII [1879], p. 105) this sign was derived from an Egyptian hieratic sign. One has also sought the origin of our sign $-$ in the sign employed by Heron and Diophantus and which changed to \top before it became $-$. Others still have advanced the view that the sign $-$ has its origin in the $\acute{o}\beta\epsilon\lambda\acute{o}\varsigma$ of the Alex-

andrian grammarians. None of these hypotheses is supported by plausible proof."¹

202. The sign $+$ first occurs in print in Widman's book in the question: "Als in diesē exēpel 16 elln pro 9 fl $\frac{1}{3}$ vñ $\frac{1}{4} + \frac{1}{5}$ eyNSS fl wy kūmē 36 elln machss also Addir $\frac{1}{3}$ vñ $\frac{1}{4}$ vñ $\frac{1}{5}$ zu sāmen kumpt $\frac{47}{60}$ eyNSS fl Nu secz vñ machss nach der regl vñ kūmē 22 fl $\frac{1}{80}$ eyNSZ fl dz ist gerad 3 hlr in gold."² In translation: "Thus in this example, 16 ells [are bought] for 9 florins [and] $\frac{1}{3}$ and $\frac{1}{4} + \frac{1}{5}$ of a florin, what will 36 ells cost? Proceed thus: Add $\frac{1}{3}$ and $\frac{1}{4}$ and $\frac{1}{5}$ obtaining $\frac{47}{60}$ of a florin. Now put down and proceed according to the rule and there results 22 florin, and $\frac{1}{80}$ of a florin which is exactly 3 heller in gold." The $+$ in this passage stands for "and." Glaisher considers this $+$ a misprint for *vñ* (the contraction for *vnnd*, our "and"), but there are other places in Widman where $+$ clearly means "and," as we shall see later. There is no need of considering this $+$ a misprint.

On the same leaf Widman gives a problem on figs. We quote from the 1498 edition (see also Fig. 54 from the 1526 edition):

¹ *Encyclopédie des scien. math.*, Tome I, Vol. I (1904), p. 31, 32, n. 145.

² Johann Widman, *Behēde vnd hubsche Rechenung auff allen Kauffmanschafft* (Leipzig, 1489), unnumbered p. 87. Our quotation is taken from J. W. L. Glaisher's article, "On the Early History of Signs $+$ and $-$ and on the Early German Arithmeticians," *Messenger of Mathematics*, Vol. LI (1921-22), p. 6. Extracts from Widman are given by De Morgan, *Transactions of the Cambridge Philosophical Society*, Vol. XI, p. 205, and by Boncompagni, *Buletino*, Vol. IX, p. 205.

"*Veygen.*—Itm Eyner Kaufft 13 lagel veygen vñ nympt ye 1 ct pro 4 fl $\frac{1}{2}$ ort Vnd wigt itliche lagel als dan hye nochuolet. vñ ich wolt wissen was an der sum brecht

	4 + 5	Wiltu dass
	4 - 17	wyszen der
	3 + 36	dess gleichñ
	4 - 19	Szo sum -
	3 + 44	mir die ct
	3 + 22	Vnd lb vñ
Czentner	3 - 11 lb	was - ist
	3 + 50	dz ist mi ⁹
	4 - 16	dz secz besū
	3 + 44	der vñ wer
	3 + 29	dē 4539
	3 - 12	lb (So du
	3 + 9	die ct zeu lb

gemacht hast Vnnd das + das ist mer dar zu addirest) vnd 75 min⁹ Nu solt du fur holez abschlahñ albeg fur eyn lagel 24 lb vñ dz ist 13 mol 24 vñ macht 312 lb dar zu addir dz - dz ist 75 lb vnnd werden 387 Die subtrahir vonn 4539 Vnnd pleybñ 4152 lb Nu sprich 100 lb das ist 1 ct pro 4 fl $\frac{1}{2}$ wie kummen 4152 lb vnd kūmen 171 fl 5 ss 4 hlr $\frac{4}{5}$ Vñ ist recht gemacht."¹

In free translation the problem reads: "*Figs.*—Also, a person buys 13 barrels of figs and receives 1 centner for 4 florins and $\frac{1}{2}$ ort ($4\frac{1}{2}$ florins), and the weight of each barrel is as follows: 4 ct + 5 lb, 4 ct - 17 lb, 3 ct + 36 lb, 4 ct - 19 lb, 3 ct + 44 lb, 3 ct + 22 lb, 3 ct - 11 lb, 3 ct + 50 lb, 4 ct - 16 lb, 3 ct + 44 lb, 3 ct + 29 lb, 3 ct - 12 lb, 3 ct + 9 lb; and I would know what they cost. To know this or the like, sum the ct and lb and what is -, that is minus, set aside, and they become 4539 lb (if you bring the centners to lb and thereto add the +, that is more) and 75 minus. Now you must subtract for the wood 24 lb for each barrel and 13 times 24 is 312 to which you add the -, that is 75 lb and it becomes 387 which subtract from 4,539 and there remains 4152 lb. Now say 100 lb that is 1 ct for $4\frac{1}{2}$ fl, what do 4152 lb come to, and they come to 171 fl 5 ss $4\frac{4}{5}$ hlr which is right."

Similar problems are given by Widman, relating to pepper and soap. The examination of these passages has led to divergent opinions on the original significance of the + and -. De Morgan suspected

¹ The passage is quoted and discussed by Eneström, *Bibliotheca mathematica*, Vol. IX (3d ser., 1908-9), p. 156, 157, 248; see also *ibid.*, Vol. VIII, p. 199.

that they were warehouse marks, expressing excess or deficiency in weights of barrels of goods.¹ M. W. Drobesch,² who was the first to point out the occurrence of the signs $+$ and $-$ in Widman, says that Widman uses them in passing, as if they were sufficiently known, merely remarking, "Was $-$ ist das ist minus vnd das $+$ das ist mer." C. I. Gerhardt,³ like De Morgan, says that the $+$ and $-$ were derived from mercantile practice.

But Widman assigned the two symbols other significations as well. In problems which he solved by false position the error has the $+$ or $-$ sign prefixed.⁴ The $-$ was used also to separate the terms of a proportion. In "11630-198 4610-78" it separates the first and second and the third and fourth terms. The "78" is the computed term, the fractional value of the fourth term being omitted in the earlier editions of Widman's arithmetic. The sign $+$ occurs in the heading "Regula augmenti $+$ decrementi" where it stands for the Latin *et* ("and"), and is not used there as a mathematical symbol. In another place Widman gives the example, "Itm eyner hat kaufft 6 eyer-2 \mathfrak{A} pro 4 \mathfrak{A} +1 ey" ("Again, someone has bought 6 eggs-2 \mathfrak{A} for 4 \mathfrak{A} +1 egg"), and asks for the cost of one egg. Here the $-$ is simply a dash separating the words for the goods from the price. From this and other quotations Glaisher concludes that Widman used $+$ and $-$ "in all the ways in which they are used in algebra." But we have seen that Widman did not restrict the signs to that usage; the $+$ was used for "and" when it did not mean addition; the $-$ was used to indicate separation. In other words, Widman does not restrict the use of $+$ and $-$ to the technical meanings that they have in algebra.

203. In an anonymous manuscript,⁵ probably written about the time when Widman's arithmetic appeared, use is made of symbolism in the presentation of algebraic rules, in part as follows:

"Conditiones circa $+$ vel $-$ in additione

$\begin{array}{l} + \text{ et } + \\ - \text{ et } - \end{array} \begin{array}{l} \rangle \\ \rangle \end{array} \text{facit } \begin{array}{l} + \\ - \end{array} \begin{array}{l} \rangle \\ \rangle \end{array} \text{addatur non sumendo respectum quis numerus sit superior.}$

³ *Geschichte der Mathematik in Deutschland* (1877), p. 36: ". . . dass diese Zeichen im kaufmännischen Verkehr üblich waren."

⁴ Glaisher, *op. cit.*, p. 15.

⁵ *Regulae Cosae vel Algebrae*, a Latin manuscript, written perhaps about 1450, but "surely before 1510," in the Vienna Library.

Si fuerit $\left\{ \begin{array}{l} + \text{ et } - \\ - \text{ et } + \end{array} \right\} \begin{array}{l} \text{simpliciter subtrahatur minor numerus a} \\ \text{majori et residuo sua ascribatur nota,}^{11} \end{array}$
and similarly for subtraction. This manuscript of thirty-three leaves is supposed to have been used by Henricus Grammateus (Heinrich Schreiber) in the preparation of his *Rechenbuch* of 1518 and by Christoff Rudolff in his *Coss* of 1525.

Grammateus² in 1518 restricts his use of + and - to technical algebra: "Vnd man braucht solche zaichen als + ist vnnd, - mynnder" ("And one uses such signs as + [which] is 'and,' - 'less' "). See Figure 56 for the reproduction of this passage from the edition of 1535. The two signs came to be used freely in all German algebras, particularly those of Grammateus, Rudolff (1525), Stifel (1544), and in Riese's manuscript algebra (1524). In a text by Eysenhut³ the + is used once in the addition of fractions; both + and - are employed many times in the *regula falsi* explained at the end of the book.

Arithmetics, more particularly commercial arithmetics, which did not present the algebraic method of solving problems, did not usually make use of the + and - symbols. L. L. Jackson says: "Although the symbols + and - were in existence in the fifteenth century, and appeared for the first time in print in Widman (1489), as shown in the illustration (p. 53), they do not appear in the arithmetics as signs of operation until the latter part of the sixteenth century. In fact, they did not pass from algebra to general use in arithmetic until the nineteenth century."⁴

204. *Spread of the + and - symbols.*—In Italy the symbols \tilde{p} and \tilde{m} served as convenient abbreviations for "plus" and "minus" at the end of the fifteenth century and during the sixteenth. In 1608 the German Clavius, residing in Rome, used the + and - in his algebra brought out in Rome (see Fig. 66). Camillo Gloriosi adopted them in his *Ad theorema geometricum* of 1613 and in his *Exercitationes mathematicae, decas I* (Naples, 1627) (§ 196). The + and - signs were used by B. Cavalieri (see Fig. 86) as if they were well known. The +

and $-$ were used in England in 1557 by Robert Recorde (Fig. 71) and in Holland in 1637 by Gillis van der Hoecke (Fig. 60). In France and Spain the German $+$ and $-$, and the Italian \tilde{p} and \tilde{m} , came in sharp competition. The German Scheubel in 1551 brought out at Paris an algebra containing the $+$ and $-$ (§ 158); nevertheless, the \tilde{p} and \tilde{m} (or the capital letters P , M) were retained by Peletier (Figs. 80, 81), Buteo (Fig. 82), and Gosselin (Fig. 83). But the adoption of the German signs by Ramus and Vieta (Figs. 84, 85) brought final victory for them in France. The Portuguese P. Nuñez (§ 166) used in his algebra (published in the Spanish language) the Italian \tilde{p} and \tilde{m} . Before this, Marco Aurel,¹ a German residing in Spain, brought out an algebra at Valencia in 1552 which contained the $+$ and $-$ and the symbols for powers and roots found in Christoff Rudolff (§ 165). But ten years later the Spanish writer Pérez de Moya returned to the Italian symbolism² with its \tilde{p} and \tilde{m} , and the use of n ., co ., ce , cu , for powers and r , rr , rrr for roots. Moya explains: "These characters I am moved to adopt, because others are not to be had in the printing office."³ Of English authors⁴ we have found only one using the Italian signs for "plus" and "minus," namely, the physician and mystic, Robert Fludd, whose numerous writings were nearly all published on the Continent. Fludd uses \mathfrak{P} and \mathfrak{M} for "plus" and "minus."

The $+$ and $-$, and the \tilde{p} and \tilde{m} , were introduced in the latter part of the fifteenth century, about the same time. They competed with each other for more than a century, and \tilde{p} and \tilde{m} finally lost out in the early part of the seventeenth century.

205. *Shapes of the plus sign.*—The plus sign, as found in print, has had three principal varieties of form: (1) the Greek cross $+$, as it is found in Widman (1489); (2) the Latin cross, \dagger more frequently placed horizontally, $+$ or $+$; (3) the form \mathfrak{X} , or occasionally some form still more fanciful, like the eight-pointed Maltese cross \mathfrak{X} , or a cross having four rounded vases with tendrils drooping from their edges.

The Greek cross, with the horizontal stroke sometimes a little

longer than the vertical one, was introduced by Widman and has been the prevailing form of plus sign ever since. It was the form commonly used by Grammateus, Rudolff, Stifel, Recorde, Digges, Clavius, Dee, Harriot, Oughtred, Rahn, Descartes, and most writers since their time.

206. The Latin cross, placed in a horizontal position, thus $—+$, was used by Vieta¹ in 1591. The Latin cross was used by Romanus,² Hunt,³ Hume,⁴ Hérigone,⁵ Mengoli,⁶ Huygens,⁷ Fermat,⁸ by writers in the *Journal des Sçavans*,⁹ Dechales,¹⁰ Rolle,¹¹ Lamy,¹² L'Hospital,¹³ Swedenborg,¹⁴ Pardies,¹⁵ Kresa,¹⁶ Belidor,¹⁷ De Moivre,¹⁸ and Michelsen.¹⁹ During the eighteenth century this form became less common and finally very rare.

Sometimes the Latin cross receives special ornaments in the form of a heavy dot at the end of each of the three shorter arms, or in the form of two or three prongs at each short arm, as in H. Vitalis.²⁰ A very ostentatious twelve-pointed cross, in which each of the four equal

arms has three prongs, is given by Carolo Renaldini.¹ In seventeenth- and eighteenth-century books it is not an uncommon occurrence to have two or three forms of plus signs in one and the same publication, or to find the Latin cross in an upright or horizontal position, according to the crowded condition of a particular line in which the symbol occurs.

207. The cross of the form $\mathbf{✞}$ was used in 1563 and earlier by the Spaniard De Hortegea,² also by Klebotius,³ Romanus,⁴ and Descartes.⁵ It occurs not infrequently in the *Acta eruditorum*⁶ of Leipzig, and sometimes in the *Miscellanea Berolinensia*.⁷ It was sometimes used by Halley,⁸ Weigel,⁹ Swedenborg,¹⁰ and Wolff.¹¹ Evidently this symbol had a wide geographical distribution, but it never threatened to assume supremacy over the less fanciful Greek cross.

A somewhat simpler form, $\mathbf{⊕}$, consists of a Greek cross with four uniformly heavy black arms, each terminating in a thin line drawn across it. It is found, for example, in a work of Hindenburg,¹² and renders the plus signs on a page unduly conspicuous.

Occasionally plus signs are found which make a "loud" display on the printed page. Among these is the eight-pointed Maltese cross,

¹ Carolo Renaldini *Ars analytica mathematicvm* (Florence, 1665), p. 80, and throughout the volume, while in the earlier edition (Anconnae, 1644) he uses both the heavy cross and dagger form.

of varying shape, found, for example, in James Gregory,¹ Corachan,² Wolff,³ and Hindenburg.⁴

Sometimes the ordinary Greek cross has the horizontal stroke very much heavier or wider than the vertical, as is seen, for instance, in Fortunatus.⁵ A form for plus —/— occurs in Johan Albert.⁶

208. *Varieties of minus signs.*—One of the curiosities in the history of mathematical notations is the fact that notwithstanding the extreme simplicity and convenience of the symbol $-$ to indicate subtraction, a more complicated symbol of subtraction \div should have been proposed and been able to maintain itself with a considerable group of writers, during a period of four hundred years. As already shown, the first appearance in print of the symbols $+$ and $-$ for “plus” and “minus” is found in Widman’s arithmetic. The sign $-$ is one of the very simplest conceivable; therefore it is surprising that a modification of it should ever have been suggested.

Probably these printed signs have ancestors in handwritten documents, but the line of descent is usually difficult to trace with certainty (§ 201). The following quotation suggests another clue: “In the west-gothic writing before the ninth century one finds, as also Paoli remarks, that a short line has a dot placed above it \div , to indicate *m*, in order to distinguish this mark from the simple line which signifies a contraction or the letter *N*. But from the ninth century down, this same west-gothic script always contains the dot over the line even when it is intended as a general mark.”⁷

In print the writer has found the sign \div for “minus” only once. It occurs in the 1535 edition of the *Rechenbüchlin* of Grammateus (Fig. 56). He says: “Vnd man brauchet solche zeichen als $+$ ist mehr / vnd \div / minder.”⁸ Strange to say, this minus sign does not occur in the first edition (1518) of that book. The corresponding passage of the earlier edition reads: “Vnd man braucht solche zaichen

als + ist vnnd / – mynnder.” Nor does Grammateus use \div in other parts of the 1535 edition; in his mathematical operations the minus sign is always $-$.

The use of the dash and two dots, thus \div , for “minus,” has been found by Glaisher to have been used in 1525, in an arithmetic of Adam Riese,¹ who explains: “Sagenn sie der warheit zuuul so bezeychenn sie mit dem zeychen + plus wu aber zu wenigk so beschreib sie mit dem zeychen \div minus genant.”²

No reason is given for the change from $-$ to \div . Nor did Riese use \div to the exclusion of $-$. He uses \div in his algebra, *Die Coss*, of 1524, which he did not publish, but which was printed³ in 1892, and also in his arithmetic, published in Leipzig in 1550. Apparently, he used $-$ more frequently than \div .

Probably the reason for using \div to designate $-$ lay in the fact that $-$ was assigned more than one signification. In Widman's arithmetic $-$ was used for subtraction or “minus,” also for separating terms in proportion,⁴ and for connecting each amount of an article (wool, for instance) with the cost per pound (§ 202). The symbol $-$ was also used as a rhetorical symbol or dash in the same manner as it is used at the present time. No doubt, the underlying motive in introducing \div in place of $-$ was the avoidance of confusion. This explanation receives support from the German astronomer Regiomontanus,⁵ who, in his correspondence with the court astronomer at Ferrara, Giovanni Bianchini, used $-$ as a sign of equality; and used for subtraction a different symbol, namely, $\overline{i}q$ (possibly a florescent form of \overline{m}). With him $1 \overline{i}q r^e$ meant $1-x$.

Eleven years later, in 1546, Gall Splenlin, of Ulm, had published at Augsburg his *Arithmetica künstlicher Rechnung*, in which he uses \div , saying: “Bedeut das zaichen + züuul, und das \div zü wenig.”⁶ Riese and Splenlin are the only arithmetical authors preceding the middle of the sixteenth century whom Glaisher mentions as using \div for subtraction or “minus.”⁷ Caspar Thierfeldern,⁸ in his *Arithmetica*

(Nuremberg, 1587), writes the equation (p. 110), "18 fl. ÷ 85 gr. gleich 25 fl. ÷ 232 gr."

With the beginning of the seventeenth century ÷ for "minus" appears more frequently, but, as far as we have been able to ascertain only in German, Swiss, and Dutch books. A Dutch teacher, Jacob Vander Schuere, in his *Arithmetica* (Haarlem, 1600), defines + and -, but lapses into using ÷ in the solution of problems. A Swiss writer, Wilhelm Schey,¹ in 1600 and in 1602 uses both ÷ and ÷÷ for "minus." He writes $9+9$, $5\div 12$, $6\div 28$, where the first number signifies the weight in *centner* and the second indicates the excess or deficiency of the respective "pounds." In another place Schey writes "9 fl. ÷÷ 1 ort," which means "9 florins less 1 ort or quart." In 1601 Nicolaus Reymers,² an astronomer and mathematician, uses regularly ÷ for "minus" or subtraction; he writes

$$\begin{array}{cccccccc} \text{"XXVIII} & \text{XII} & \text{X} & \text{VI} & \text{III} & \text{I} & \text{O} & \\ 1 \text{ gr.} & 65532+18 & \div 30 & \div 18 & +12 & \div 8 & " & \\ \text{for } x^{28}=65,532x^{12}+18x^{10}-30x^6-18x^3+12x-8. & & & & & & & \end{array}$$

Peter Roth, of Nürnberg, uses ÷÷ in writing³ $3x^2-26x$. Johannes Faulhaber⁴ at Ulm in Württemberg used ÷ frequently. With him the horizontal stroke was long and thin, the dots being very near to it. The year following, the symbol occurs in an arithmetic of Ludolf van Ceulen,⁵ who says in one place: "Subtraheert $\sqrt{7}$ van, $\sqrt{13}$, rest $\sqrt{13}$, weynigher $\sqrt{7}$, daerom stelt $\sqrt{13}$ voren en $\sqrt{7}$ achter, met een sulck teecken ÷ tusschen beyde, vvelek teecmin beduyt, comt alsoo de begerde rest $\sqrt{13}\div\sqrt{7}$ —." However, in some parts of the book — is used for subtraction. Albert Girard⁶ mentions ÷ as the symbol for "minus," but uses —. Otto Wesellow⁷ brought out a book in which

$+$ and \div stand for "plus" and "minus," respectively. These signs are used by Follinus,¹ by Stampioen (§ 508), by Daniel van Hovcke² who speaks of $+$ as signifying "mer en \div min.," and by Johann Ardüser³ in a geometry. It is interesting to observe that only thirteen years after the publication of Ardüser's book, another Swiss, J. H. Rahn, finding, perhaps, that there existed two signs for subtraction, but none for division, proceeded to use \div to designate division. This practice did not meet with adoption in Switzerland, but was seized upon with great avidity as the symbol for division in a far-off country, England. In 1670 \div was used for subtraction once by Huygens⁴ in the *Philosophical Transactions*. Johann Hemelings⁵ wrote \div for "minus" and indicated, in an example, $14\frac{1}{2}$ legions less 1250 men by "14 $\frac{1}{2}$ Legion \div 1250 Mann." The symbol is used by Tobias Beutel,⁶ who writes " $81 \div 1R6561 \div 162$. R. + 1. zenss" to represent our $81 - \sqrt{6561 - 162x + x^2}$. Kegel⁷ explains how one can easily multiply by 41, by first multiplying by 6, then by 7, and finally subtracting the multiplicand; he writes " $7 \div 1$." In a set of seventeenth-century examination questions used at Nürnberg, reference is made to cossic operations involving quantities, "durch die Signa $+$ und \div connectirt."⁸

The vitality of this redundant symbol of subtraction is shown by its continued existence during the eighteenth century. It was employed by Paricius,⁹ of Regensburg. Schlessler¹⁰ takes \div to represent

"minus oder weniger." It was employed in the *Philosophical Transactions* by the Dutch astronomer N. Cruquius;¹ \div is found in Hübsch² and Crusius.³ It was used very frequently as the symbol for subtraction and "minus" in the *Maandelykse Mathematische Liefhebbery*, Purmerende (1754–69). It is found in a Dutch arithmetic by Bartjens⁴ which passed through many editions. The vitality of the symbol is displayed still further by its regular appearance in a book by van Steyn,⁵ who, however, uses $-$ in 1778.⁶ Halcke states, " \div of $-$ het teken van *subtractio minus* of min.,"⁷ but uses $-$ nearly everywhere. Praalder, of Utrecht, uses ordinarily the minus sign $-$, but in one place⁸ he introduces, for the sake of clearness, as he says, the use of \div to mark the subtraction of complicated expressions. Thus, he writes " $= \div 9\frac{1}{2} + 2\sqrt{26}$." The \div occurs in a Leipzig magazine,⁹ in a Dresden work by Illing,¹⁰ in a Berlin text by Schmeisser,¹¹ who uses it also in expressing arithmetical ratio, as in " $2 \div 6 \div 10$." In a part of Klügel's¹² mathematical dictionary, published in 1831, it is stated that \div is used as a symbol for division, "but in German arithmetics is employed also to designate subtraction." A later use of it for "minus," that we have noticed, is in a Norwegian arithmetic.¹³ In fact, in Scandinavian

countries the sign \div for "minus" is found occasionally in the twentieth century. For instance, in a Danish scientific publication of the year 1915, a chemist expresses a range of temperature in the words "fra $+18^{\circ}$ C. til $\div 18^{\circ}$ C."¹ In 1921 Ernst W. Selmer² wrote " $0,72 \div 0,65 = 0,07$." The difference in the dates that have been given, and the distances between the places of publication, make it certain that this symbol \div for "minus" had a much wider adoption in Germany, Switzerland, Holland, and Scandinavia than the number of our citations would indicate. But its use seems to have been confined to Teutonic peoples.

Several writers on mathematical history have incidentally called attention to one or two authors who used the symbol \div for "minus," but none of the historians revealed even a suspicion that this symbol had an almost continuous history extending over four centuries.

209. Sometimes the minus sign $-$ appears broken up into two or three successive dashes or dots. In a book of 1610 and again of 1615, by Ludolph van Ceulen,³ the minus sign occasionally takes the form $--$. Richard Balam⁴ uses three dots and says " $3 \cdot \cdot \cdot 7$, 3 from 7"; he writes an arithmetical proportion in this manner: " $2 \cdot \cdot \cdot 4 = 3 \cdot \cdot \cdot 5$." Two or three dots are used in René Descartes' *Géométrie*, in the writings of Marin Mersenne,⁵ and in many other seventeenth-century books, also in the *Journal des Sçavans* for the year 1686, printed in Amsterdam, where one finds (p. 482) " $1 --- R --- 11$ " for $1 - \sqrt{-11}$, and in volumes of that *Journal* printed in the early part of the eighteenth century. Hérigone used \sim for "minus" (§ 189), the $-$ being pre-empted for *recta linea*.

From these observations it is evident that in the sixteenth and seventeenth centuries the forms of type for "minus" were not yet standardized. For this reason, several varieties were sometimes used on the same page.

This study emphasizes the difficulty experienced even in ordinary

arithmetic and algebra in reaching a common world-language. Centuries slip past before any marked step toward uniformity is made. It appears, indeed, as if blind chance were an uncertain guide to lead us away from the Babel of languages. The only hope for rapid approach of uniformity in mathematical symbolism lies in international co-operation through representative committees.

210. *Symbols for "plus or minus."*—The \pm to designate "plus or minus" was used by Albert Girard in his *Tables*¹ of 1626, but with the interpolation of *ou*, thus " $\overset{+}{ou}$." The \pm was employed by Oughtred in his *Clavis mathematicae* (1631), by Wallis,² by Jones³ in his *Synopsis*, and by others. There was considerable experimentation on suitable notations for cases of simultaneous double signs. For example, in the third book of his *Géométrie*, Descartes uses a dot where we would

write \pm . Thus he writes the equation " $+y^6 \cdot 2py^4 \overset{+pp}{4ryy} - qq \approx 0$ " and then comments on this: "Et pour les signes $+$ ou $-$ que iay omis, s'il y a eu $+p$ en la precedente Equation, il faut mettre en celle $-cy + 2p$, ou s'il ya eu $-p$, il faut mettre $-2p$; & au contraire s'il ya eu $+r$, il faut mettre $-4r$, ..." The symbolism which in the *Miscellanea Berolinensia* of 1710 is attributed to Leibniz is given in § 198.

A different notation is found in Isaac Newton's *Universal Arithmetick*: "I denoted the Signs of b and c as being indeterminate by the Note \perp , which I use indifferently for $+$ or $-$, and its opposite \top for the contrary."⁴ These signs appear to be the $+$ with half of the vertical stroke excised. William Jones, when discussing quadratic equations, says: "Therefore if \vee be put for the Sign of any Term, and \wedge for the contrary, all *Forms of Quadratics* with their *Solutions*, will be reduc'd to this one. If $xx \vee ax \vee b = 0$ then $\wedge \frac{1}{2}a \pm aa \wedge b \Big|^{1/2}$."⁵ Later in the book (p. 189) Jones lets two horizontal dots represent any sign: "Suppose any *Equation* whatever, as $x^n \dots ax^{n-1} \dots bx^{n-2} \dots cx^{n-3} \dots dx^{n-4}$, etc. $\dots A = 0$."

A symbol $\&$ standing for \pm was used in 1649 and again as late as 1695, by van Schooten⁶ in his editions of Descartes' geometry, also

by De Witt.¹ Wallis² wrote \times for $+$ or $-$, and $\&$ for the contrary. The sign $\&$ was used in a restricted way, by James Bernoulli;³ he says, " $\&$ significat $+$ in pr. e $-$ in post. hypoth.," i.e., the symbol stood for $+$ according to the first hypothesis, and for $-$, according to the second hypothesis. He used this same symbol in his *Ars conjectandi* (1713), page 264. Van Schooten wrote also \times for \mp . It should be added that \times appears also in the older printed Greek books as a ligature or combination of two Greek letters, the omicron \omicron and the upsilon υ . The \times appears also as an astronomical symbol for the constellation Taurus.

Da Cunha⁴ introduced \pm' and \pm'' , or \pm' and \mp' , to mean that the upper signs shall be taken simultaneously in both or the lower signs shall be taken simultaneously in both. Oliver, Wait, and Jones⁵ denoted positive or negative N by $\pm N$.

211. The symbol $[a]$ was introduced by Kronecker⁶ to represent 0 or $+1$ or -1 , according as a was 0 or $+1$ or -1 . The symbol "sgn" has been used by some recent writers, as, for instance, Peano,⁷ Netto,⁸ and Le Vavas seur, in a manner like this: " $\text{sgn } A = +1$ " when $A > 0$, " $\text{sgn } A = -1$ " when $A < 0$. That is, " $\text{sgn } A$ " means the "sign of A ." Similarly, Kowalewski⁹ denotes by " $\text{sgn } \mathfrak{P}$ " $+1$ when \mathfrak{P} is an even, and -1 when \mathfrak{P} is an odd, permutation.

The symbol $\sqrt{a^2}$ is sometimes taken in the sense¹⁰ $\pm a$, but in equations involving $\sqrt{\quad}$, the principal root $+a$ is understood.

212. *Certain other specialized uses of $+$ and $-$.*—The use of each of the signs $+$ and $-$ in a double sense—first, to signify addition and subtraction; second, to indicate that a number is positive and negative—has met with opposition from writers who disregarded the advantages resulting from this double use, as seen in $a - (-b) = a + b$,

and who aimed at extreme logical simplicity in expounding the elements of algebra to young pupils. As a remedy, German writers proposed a number of new symbols which are set forth by Schmeisser as follows:

"The use of the signs $+$ and $-$, not only for opposite magnitudes . . . but also for Addition and Subtraction, frequently prevents clearness in these matters, and has even given rise to errors. For that reason other signs have been proposed for the positive and negative. Wilkins (*Die Lehre von d. entgegengesetzt. Grössen etc.*, Brschw., 1800) puts down the positive without signs ($+a=a$) but places over the negative a dash, as in $-a=\bar{a}$. v. Winterfeld (*Anfangsgr. d. Rechenk.*, 2te Aufl. 1809) proposes for positive the sign \vdash or Γ , for negative \dashv or \neg . As more scientific he considers the inversion of the letters and numerals, but unfortunately some of them as i , r , o , x , etc., and 0 , 1 , 8 , etc., cannot be inverted, while others, by this process, give rise to other letters as b , d , p , q , etc. Better are the more recent proposals of Winterfeld, to use for processes of computation the signs of the waxing and waning moon, namely for Addition \smile , for Subtraction \frown , for Multiplication \bowtie , for Division \complement , but as he himself acknowledges, even these are not perfectly suitable. . . . Since in our day one does not yet, for love of correctness, abandon the things that are customary though faulty, it is for the present probably better to stress the significance of the concepts of the positive and additive, and of the negative and subtractive, in instruction, by the retention of the usual signs, or, what is the same thing, to let the qualitative and quantitative significance of $+$ and $-$ be brought out sharply. This procedure has the advantage moreover of more fully exercising the understanding."¹

Wolfgang Bolyai² in 1832 draws a distinction between $+$ and $-$, and \vdash and \dashv ; the latter meaning the (intrinsic) "positive" and "negative." If A signifies $\dashv B$, then $-A$ signifies $\vdash B$.

213. In more recent time other notations for positive and negative numbers have been adopted by certain writers. Thus, Spitz³ uses $\leftarrow a$ and $\rightarrow a$ for positive a and negative a , respectively. Méray⁴ prefers \vec{a} , \bar{a} ; Padé,⁵ a_p , a_n ; Oliver, Wait, and Jones⁶ employ an ele-

⁶ *Op. cit.*, p. 5.

vated + or - (as in +10, -10) as signs of "quality"; this practice has been followed in developing the fundamental operations in algebra by a considerable number of writers; for instance, by Fisher and Schwatt,¹ and by Slaught and Lennes.² In elementary algebra the special symbolisms which have been suggested to represent "positive number" or "negative number" have never met with wide adoption. Stolz and Gmeiner³ write a , \bar{a} , for positive a and negative a . The designation . . . -3, -2, -1, 0, +1, +2, +3, . . . , occurs in Huntington's *Continuum* (1917), page 20.

214. A still different application of the sign + has been made in the theory of integral numbers, according to which Peano⁴ lets $a+$ signify the integer immediately following a , so that $a+$ means the integer $(a+1)$. For the same purpose, Huntington⁵ and Stolz and Gmeiner⁶ place the + in the position of exponents, so that $5^+=6$.

215. *Four unusual signs.*—The Englishman Philip Ronayne used in his *Treatise of Algebra* (London, 1727; 1st ed., 1717), page 4, two curious signs which he acknowledged were "not common," namely, the sign \ominus to denote that "some Quantity indefinitely Less than the Term that next precedes it, is to be added," and the sign $\omin�$ that such a quantity is "to be subtracted," while the sign \oplus may mean "either \ominus or $\omin�$ when it matters not which of them it is." We have not noticed these symbols in other texts.

How the progress of science may suggest new symbols in mathematics is illustrated by the composition of velocities as it occurs in Einstein's addition theorem.⁷ Silberstein uses here \sharp instead of +.

216. *Composition of ratios.*—A strange misapplication of the + sign is sometimes found in connection with the "composition" of ratios. If the ratios $\frac{NP}{CN}$ and $\frac{AN}{CN}$ are multiplied together, the product

⁶ Op. cit., Vol. I, p. 14. In the first edition Peano's notation was used.

⁷ C. E. Weatherburn, *Advanced Vector Analysis* (London, 1924), p. xvi.

$\frac{NP}{CN} \cdot \frac{AN}{CN}$, according to an old phraseology, was "compounded" of the first two ratios.¹ Using the term "proportion" as synonymous with "ratio," the expression "composition of proportions" was also used. As the word "composition" suggests addition, a curious notation, using +, was at one time employed. For example, Isaac Barrow² denoted the "compounded ratio" $\frac{NP}{CN} \cdot \frac{AN}{CN}$ in this manner, " $NP \cdot CN + AN \cdot CN$." That is, the sign of addition was used in place of a sign of multiplication, and the dot signified ratio as in Oughtred.

In another book³ Barrow again multiplies equal ratios by equal ratios. In modern notation, the two equalities are

$$(PL+QO):QO=2BC:(BC-CP) \text{ and } QO:BC=BC:(BC+CP) .$$

Barrow writes the result of the multiplication thus:

$$PL+QO \cdot QO+QO \cdot BC=2BC \cdot BC-CP+BC \cdot BC+CP .$$

Here the + sign occurs four times, the first and fourth times as a symbol of ordinary addition, while the second and third times it occurs in the "addition of equal ratios" which really means the multiplication of equal ratios. Barrow's final relation means, in modern notation,

$$\frac{PL+QO}{QO} \cdot \frac{QO}{BC} = \frac{2BC}{BC-CP} \cdot \frac{BC}{BC+CP} .$$

Wallis, in his *Treatise of Algebra* (London, 1685), page 84, comments on this subject as follows: "But now because *Euclide* gives to this the name of *Composition*, which word is known many times to impart an *Addition*; (as when we say the Line *ABC* is compounded of *AB* and *BC*;) some of our more ancient Writers have chanced to call it *Addition of Proportions*; and others, following them, have continued that form of speech, which abides in (in divers Writers) even to this day: And the Dissolution of this composition they call *Subduction of Proportion*. (Whereas that should rather have been called *Multiplication*, and this *Division*.)"

A similar procedure is found as late as 1824 in J. F. Lorenz' trans-

¹ See Euclid, *Elements*, Book VI, Definition 5. Consult also T. L. Heath, *The Thirteen Books of Euclid's "Elements,"* Vol. II (Cambridge, 1908), p. 132-35, 189, 190.

lation from the Greek of Euclid's *Elements* (ed. C. B. Mollweide; Halle, 1824), where on page 104 the Definition 5 of Book VI is given thus: "Of three or more magnitudes, A, B, C, D , which are so related to one another that the ratios of any two consecutive magnitudes $A:B, B:C, C:D$, are equal to one another, then the ratio of the first magnitude to the last is said to be *composed* of all these ratios so that $A:D = (A:B) + (B:C) + (C:D)$ " (in modern notation, $\frac{A}{D} = \frac{A}{B} \cdot \frac{B}{C} \cdot \frac{C}{D}$).

SIGNS OF MULTIPLICATION

217. *Early symbols.*—In the early Babylonian tablets there is, according to Hilprecht,¹ an ideogram $A-DU$ signifying "times" or multiplication. The process of multiplication or division was known to the Egyptians² as *wshtp*, "to incline the head"; it can hardly be regarded as being a mathematical symbol. Diophantus used no symbol for multiplication (§ 102). In the Bakhshālī manuscript multiplication is usually indicated by placing the numbers side by side (§ 109). In some manuscripts of Bhāskara and his commentators a dot is placed between factors, but without any explanation (§ 112). The more regular mark for product in Bhāskara is the abbreviation *bha*, from *bhavita*, placed after the factors (§ 112).

Stifel in his *Deutsche Arithmetica* (Nürnberg, 1545) used the capital letter M to designate multiplication, and D to designate division. These letters were again used for this purpose by S. Stevin³ who expresses our $3xyz^2$ thus: $3 \textcircled{1} M \textcircled{2} sec \textcircled{1} M \textcircled{2} ter \textcircled{2}$, where *sec* and *ter* mean the "second" and "third" unknown quantities.

The M appears again in an anonymous manuscript of 1638 explaining Descartes' *Géométrie* of 1637, which was first printed in 1896;⁴ also once in the Introduction to a book by Bartholinus.⁵

Vieta indicated the product of A and B by writing " A in B " (Fig. 84). Mere juxtaposition signified multiplication in the Bakhshālī tract, in some fifteenth-century manuscripts, and in printed algebras designating $6x$ or $5x^2$; but $5\frac{1}{2}$ meant $5 + \frac{1}{2}$, not $5 \times \frac{1}{2}$.

218. *Early uses of the St. Andrew's cross, but not as a symbol of multiplication of two numbers.*—It is well known that the St. Andrew's cross (\times) occurs as the symbol for multiplication in W. Oughtred's *Clavis mathematicae* (1631), and also (in the form of the letter X) in an anonymous Appendix which appeared in E. Wright's 1618 edition of John Napier's *Descriptio*. This Appendix is very probably from the pen of Oughtred. The question has arisen, Is this the earliest use of \times to designate multiplication? It has been answered in the negative—incorrectly so, we think, as we shall endeavor to show.

In the *Encyclopédie des sciences mathématiques*, Tome I, Volume I (1904), page 40, note 158, we read concerning \times , "One finds it between factors of a product, placed one beneath the other, in the Commentary added by Oswald Schrekenfuchs to Ptolemy's *Almagest*, 1551."¹ As will be shown more fully later, this is not a correct interpretation of the symbolism. Not two, but four numbers are involved, two in a line and two others immediately beneath, thus:

$$\begin{array}{cc} 315172 & 295448 \\ & \times \\ 395093 & 174715 \end{array}$$

The cross does not indicate the product of any two of these numbers, but each bar of the cross connects two numbers which are multiplied. One bar indicates the product of 315172 and 174715, the other bar the product of 395093 and 295448. Each bar is used as a symbol singly; the two bars are not considered here as one symbol.

Another reference to the use of \times before the time of Oughtred is made by E. Zirkel,² of Heidelberg, in a brief note in which he protests against attributing the "invention" of \times to Oughtred; he states that it had a period of development of over one hundred years. Zirkel does

¹ *Clavdii Ptolemaei Pelusiensis Alexandrini Omnia quae extant Opera* (Basileae, 1551), Lib. ii, "Annotationes."

² Emil Zirkel, *Zeitschr. f. math. u. naturw. Unterricht*, Vol. LII (1921), p. 96. An article on the sign \times , which we had not seen before the time of proofreading, when R. C. Archibald courteously sent it to us, is written by N. L. W. A. Gravelaar in *Wiskundig Tijdschrift*, Vol. VI (1909-10), p. 1-25. Gravelaar cites a few writers whom we do not mention. His claim that, before Oughtred, the sign \times occurred as a sign of multiplication, must be rejected as not borne out by the facts. It is one thing to look upon \times as two symbols, each indicating a separate operation, and quite another thing to look upon \times as only one symbol indicating only one operation. This remark applies even to the case in § 229, where the four numbers involved are conveniently placed at the four ends of the cross, and each stroke connects two numbers to be subtracted one from the other.

not make his position clear, but if he does not mean that \times was used before Oughtred as a sign of multiplication, his protest is pointless.

Our own studies have failed to bring to light a clear and conclusive case where, before Oughtred, \times was used as a symbol of multiplication. In medieval manuscripts and early printed books \times was used as a mathematical sign, or a combination of signs, in eleven or more different ways, as follows: (1) in solutions of problems by the process of two false positions, (2) in solving problems in compound proportion involving integers, (3) in solving problems in simple proportion involving fractions, (4) in the addition and subtraction of fractions, (5) in the division of fractions, (6) in checking results of computation by the processes of casting out the 9's, 7's, or 11's, (7) as part of a group of lines drawn as guides in the multiplication of one integer by another, (8) in reducing radicals of different orders to radicals of the same order, (9) in computing on lines, to mark the line indicating "thousands," (10) to take the place of the multiplication table above 5 times 5, and (11) in dealing with amicable numbers. We shall briefly discuss each of these in order.

219. *The process of two false positions.*—The use of \times in this process is found in the *Liber abbaci* of Leonardo¹ of Pisa, written in 1202. We must begin by explaining Leonardo's use of a single line or bar. A line connecting two numbers indicates that the two numbers are to be multiplied together. In one place he solves the problem: If 100 *rotuli* are worth 40 *libras*, how many *libras* are 5 *rotuli* worth? On the margin of the sheet stands the following:

<i>l.</i>	<i>R.</i>
40	100
—	5 <i>R.</i>

The line connecting 40 and 5 indicates that the two numbers are to be multiplied together. Their product is divided by 100, but no symbolism is used to indicate the division. Leonardo uses single lines over a hundred times in the manner here indicated. In more complicated problems he uses two or more lines, but they do not necessarily

¹ Leonardo of Pisa, *Liber abbaci* (1202) (ed. B. Boncompagni; Roma, 1857), Vol. I, p. 84.

form crosses. In a problem involving five different denominations of money he gives the following diagram:¹

<i>barcellon.</i>	<i>turn.</i>	<i>Ian.</i>	<i>pisan.</i>	<i>imp.</i>
$\frac{3}{11} \frac{3}{13} \frac{8}{13} 20$	12	13	31	12
<i>barcellon.</i>	<i>turn.</i>	<i>Ian.</i>	<i>pisan.</i>	<i>imp.</i>
12	11	12	23	15

Here the answer 20+ is obtained by taking the product of the connected numbers and dividing it by the product of the unconnected numbers.

Leonardo uses a cross in solving, by double false position, the problem: If 100 *rotuli* cost 13 *libras*, find the cost of 1 *rotulus*. The answer is given in *solidi* and *denarii*, where 1 *libra* = 20 *solidi*, 1 *solidus* = 12 *denarii*. Leonardo assumes at random the tentative answers (the two false positions) of 3 *solidi* and 2 *solidi*. But 3 *solidi* would make this cost of 100 *rotuli* 15 *libra*, an error of +2 *libras*; 2 *solidi* would make the cost 10, an error of -3. By the underlying theory of two false positions, the errors in the answers (i.e., the errors $x-3$ and $x-2$ *solidi*) are proportional to the errors in the cost of 100 *rotuli* (i.e., +2 and -3 *libras*); this proportion yields $x=2$ *solidi* and $7\frac{1}{5}$ *denarii*. If the reader will follow out the numerical operations for determining our x he will understand the following arrangement of the work given by Leonardo (p. 319):

"Additum ex 13 multiplicationibus

4	9
<i>solidi</i>	<i>solidi</i>
2	3
minus	plus
3	2
	5

Additum ex erroribus."

Observe that Leonardo very skilfully obtains the answer by multiplying each pair of numbers connected by lines, thereby obtaining the products 4 and 9, which are added in this case, and then dividing 13 by 5 (the sum of the errors). The cross occurring here is not one symbol, but two symbols. Each line singly indicates a multiplication. It would be a mistake to conclude that the cross is used here as a symbol expressing multiplication.

¹ *Ibid.*, Vol. I, p. 127.

The use of two lines crossing each other, in double or single false position, is found in many authors of later centuries. For example, it occurs in MS 14908 in the Munich Library,¹ written in the interval 1455–64; it is used by the German Widman,² the Italian Pacioli,³ the Englishman Tonstall,⁴ the Italian Sfortunati,⁵ the Englishman Recorde,⁶ the German Splenlin,⁷ the Italians Ghaligai⁸ and Benedetti,⁹ the Spaniard Hortega,¹⁰ the Frenchman Trenchant,¹¹ the Dutchman Gemma Frisius,¹² the German Clavius,¹³ the Italian Tartaglia,¹⁴ the Dutchman Snell,¹⁵ the Spaniard Zaragoza,¹⁶ the Britishers Jeake¹⁷ and

Wingate,¹ the Italian Guido Grandi,² the Frenchman Chalosse,³ the Austrian Steinmeyer,⁴ the Americans Adams⁵ and Preston.⁶ As a sample of a seventeenth-century procedure, we give Schott's solution⁷ of $\frac{x}{2} - \frac{x}{6} - \frac{x}{8} = 30$. He tries $x=24$ and $x=48$. He obtains errors -25 and -20 . The work is arranged as follows:

24.	X	48.	Dividing $48 \times 25 - 24 \times 20$ by 5 gives $x=144$.
M.		M.	
25.	5.	20.	

220. *Compound proportion with integers*.—We begin again with Leonardo of Pisa (1202)⁸ who gives the problem: If 5 horses eat 6 quarts of barley in 9 days, for how many days will 16 quarts feed 10 horses? His numbers are arranged thus:

The answer is obtained by dividing $9 \times 16 \times 5$ by the product of the remaining known numbers. Answer 12.

Somewhat different applications of lines crossing each other are given by Nicolas Chuquet⁹ and Luca Pacioli¹⁰ in dealing with numbers in continued proportion.

¹⁰ Luca Pacioli, *op. cit.*, fol. 93a.

Chuquet finds two mean proportionals between 8 and 27 by the scheme

$$\begin{array}{ccc}
 \text{" } 8 & & 27 \\
 2 & \searrow & 3 \\
 4 & \swarrow & 9 \\
 \hline
 12 & & 18 \text{ " }
 \end{array}$$

where 12 and 18 are the two mean proportionals sought; i.e., 8, 12, 18, 27 are in continued proportion.

221. *Proportions involving fractions*.—Lines forming a cross (\times), together with two horizontal parallel lines, were extensively applied to the solution of proportions involving fractions, and constituted a most clever device for obtaining the required answer mechanically. If it is the purpose of mathematics to resolve complicated problems by a minimum mental effort, then this device takes high rank.

The very earliest arithmetic ever printed, namely, the anonymous booklet gotten out in 1478 at Treviso,¹ in Northern Italy, contains an interesting problem of two couriers starting from Rome and Venice, respectively, the Roman reaching Venice in 7 days, the Venetian arriving at Rome in 9 days. If Rome and Venice are 250 miles apart, in how many days did they meet, and how far did each travel before they met? They met in $3\frac{1}{2}$ days. The computation of the distance traveled by the courier from Rome calls for the solution of the proportion which we write $7:250 = \frac{7}{9} : x$.

The Treviso arithmetic gives the following arrangement:

$$\begin{array}{ccc}
 112 & & \\
 7 & \searrow & 250 \text{ --- } 63 \\
 1 & \swarrow & 1 \text{ --- } 16
 \end{array}$$

The connecting lines indicate what numbers shall be multiplied together; namely, 1, 250, and 63, also 7, 1, and 16. The product of the latter—namely, 112—is written above on the left. The author then finds $250 \times 63 = 15,750$ and divides this by 112, obtaining $140\frac{1}{2}$ miles.

These guiding lines served as Ariadne threads through the maze of a proportion involving fractions.

We proceed to show that this magical device was used again by Chuquet (1484), Widman (1489), and Pacioli (1494). Thus Chuquet²

¹ The Treviso arithmetic of 1478 is described and partly given in facsimile by Boncompagni in *Atti dell'Accademia Pontificia de' nuovi Lincei*, Tome XVI (1862-63; Roma, 1863), see p. 568.

² Chuquet, in Boncompagni, *Bullettino*, Vol. XIII, p. 636; reprint, p. (84).

uses the cross in the problem to find two numbers in the ratio of $\frac{3}{4}$ to $\frac{3}{4}$ and whose sum is 100. He writes $\begin{array}{r} 3 \quad 2 \\ - \quad - \\ 4 \quad 3 \end{array}$; multiplying 3 by 3,

and 2 by 4, he obtains two numbers in the proper ratio. As their sum is only 17, he multiplies each by $\frac{100}{17}$ and obtains $47\frac{1}{17}$ and $52\frac{1}{17}$.

Johann Widman¹ solves the proportion $9 : \frac{53}{8} = \frac{89}{8} : x$ in this man-

ner: "Secz also $\begin{array}{r} 9 \quad 53 \text{ — } 89 \\ - \quad - \quad - \\ 1 \quad 8 \quad 8 \end{array}$ machss nach der Regel vnd küpt 8 fl.

35s 9 helr $\frac{5}{8}$." It will be observed that the computer simply took the products of the numbers connected by lines. Thus $1 \times 53 \times 89 = 4,717$ gives the numerator of the fourth term; $9 \times 8 \times 8 = 576$ gives the denominator. The answer is 8 florins and a fraction.

Such settings of numbers are found in Luca Pacioli,² Ch. Rudolph,³ G. Sfortunati,⁴ O. Schreckenfuchs,⁵ Hortege,⁶ Tartaglia,⁷ M. Steinmetz,⁸ J. Trenchant,⁹ Hermann Follinus,¹⁰ J. Alsted,¹¹ P. Hérigone,¹² Chalosse,¹³ J. Perez de Moya,¹⁴ It is remarkable that in England neither Tostall nor Recorde used this device. Recorde¹⁵ and Leonard Digges¹⁶

¹⁶ (Leonard Digges), *A Geometrical Practical Treatise named Pantometria* (London, 1591).

use a slightly different and less suggestive scheme, namely, the capital letter *Z* for proportions involving either integers or fractions. Thus, $3:8=16:x$ is given by Recorde in the form $\begin{smallmatrix} 3 \\ 8 \end{smallmatrix} \text{Z} \begin{smallmatrix} 16 \\ \end{smallmatrix}$. This rather unusual notation is found much later in the *American Accountant* of Chauncey Lee (Lansinburgh, 1797, p. 223) who writes,

$$\begin{array}{ccc} \text{"Cause"} & & \text{Effect"} \\ 4.5 \text{ yds.} & \text{Z} & 18 \\ & 90 \text{Z} & Q \end{array}$$

and finds $Q=90 \times 18 \div 4.5=360$ dollars.

222. *Addition and subtraction of fractions.*—Perhaps even more popular than in the solution of proportion involving fractions was the use of guiding lines crossing each other in the addition and subtraction of fractions. Chuquet¹ represents the addition of $\frac{2}{3}$ and $\frac{4}{5}$ by the following scheme:

$$\begin{array}{cc} \text{" 10 } & \text{ 12 " } \\ \hline & \\ 2 & 4 \\ \hline & \\ 3 & 5 \\ \hline \cdot 15 \cdot \end{array}$$

The lower horizontal line gives $3 \times 5=15$; we have also $2 \times 5=10$, $3 \times 4=12$; hence the sum $\frac{2}{3} + \frac{4}{5} = 1\frac{7}{15}$.

The same line-process is found in Pacioli,² Rudolph,³ Apianus.⁴ In England, Tonstall and Recorde do not employ this intersecting line-system, but Edmund Wingate⁵ avails himself of it, with only slight variations in the mode of using it. We find it also in Oronce Fine,⁶ Feliciano,⁷ Schreckenfuchs,⁸ Hortega,⁹ Baëza,¹⁰ the Italian

223. *Division of fractions*.—Less frequent than in the preceding processes is the use of lines in the multiplication or division of fractions, which called for only one of the two steps taken in solving a proportion involving fractions. Pietro Borgi (1488)¹⁵ divides $\frac{3}{4}$ by $\frac{1}{4}$

thus: $\frac{4}{5} \times \frac{3}{4} = \frac{15}{16}$. In dividing $\frac{1}{2}$ by $\frac{1}{3}$, Pacioli¹⁶ writes

$$\begin{array}{cc} \text{"2"} & \text{"3"} \\ \frac{1}{3} & \times \frac{1}{2} \end{array}$$

and obtains $\frac{3}{2}$ or $1\frac{1}{2}$.

Petrus Apianus (1527) uses the \times in division. Juan de Hortegea (1552)¹⁷ divides $\frac{3}{8}$ by $\frac{5}{6}$, according to the following scheme:

$$\begin{array}{ccc} \text{"} & \frac{3}{8} & \frac{18}{40} \\ & \times \frac{5}{6} & \\ & \frac{15}{40} & \end{array} \quad \text{valê } \frac{9}{20} \text{"}$$

¹⁶ L. Pacioli, *op. cit.* (1523), fol. 54a.

¹⁷ Juan de Hortegea, *op. cit.* (1552), fol. 66a.

We find this use of \times in division in Sfortunati,¹ Blundeville,² Steinmetz,³ Ludolf van Ceulen,⁴ De Graaf,⁵ Samuel Jeake,⁶ and J. Perez de Moya.⁷ De la Chapelle, in his list of symbols,⁸ introduces \times as a regular sign of division, *divisé par*, and \times as a regular sign of multiplication, *multiplié par*. He employs the latter regularly in multiplication, but he uses the former only in the division of fractions, and he explains that in $\frac{3}{4} \times \frac{4}{3} = \frac{3}{3}$, "le sautoir \times montre que 4 doit multiplier 6 & que 3 doit multiplier 7," thus really looking upon \times as two symbols, one placed upon the other.

224. In the multiplication of fractions Apianus⁹ in 1527 uses the parallel horizontal lines, thus, $\frac{1-3}{2-5}$. Likewise, Michael Stifel¹⁰ uses two horizontal lines to indicate the steps. He says: "Multiplica numeratores inter se, et proveniet numerator productae summae. Multiplica etiam denominatores inter se, et proveniet denominator productae summae."

225. *Casting out the 9's, 7's, or 11's.*—Checking results by casting out the 9's was far more common in old arithmetics than by casting out the 7's or 11's. Two intersecting lines afforded a convenient grouping of the four results of an operation. Sometimes the lines appear in the form \times , at other times in the form $+$. Luca Pacioli¹¹ divides 97535399 by 9876, and obtains the quotient 9876 and remainder 23. Casting out the 7's (i.e., dividing a number by 7 and noting the residue), he obtains for 9876 the residue 6, for 97535399 the residue 3, for 23 the residue 2. He arranges these residues thus: $\begin{array}{c} 6|2 \\ 6|3 \end{array}$.

Observe that multiplying the residues of the divisor and quotient, 6 times 6 = 36, one obtains 1 as the residue of 36. Moreover, 3 - 2 is also 1. This completes the check.

¹⁰ M. Stifel, *Arithmetica integra* (Nuremberg, 1544), fol. 6.

¹¹ Luca Pacioli, *op. cit.* (1523), fol. 35.

Nicolas Tartaglia¹ checks, by casting out the 7's, the division $912345 \div 1987 = 459$ and remainder 312.

Casting the 7's out of 912345 gives 0, out of 1987 gives 6, out of 459 gives 4, out of 312 gives 4. Tartaglia writes down $\begin{array}{r} 4 \\ 6 \end{array}$.

Here 4 times 6 = 24 yields the residue 3; 0 minus 4, or better 7 minus 4, yields 3 also. The result "checks."

Would it be reasonable to infer that the two perpendicular lines + signified multiplication? We answer "No," for, in the first place, the authors do not state that they attached this meaning to the symbols and, in the second place, such a specialized interpretation does not apply to the other two residues in each example, which are to be *subtracted* one from the other. The more general interpretation, that the lines are used merely for the convenient grouping of the four residues, fits the case exactly.

Rudolph² checks the multiplication 5678 times 65 = 369070 by casting out the 9's (i.e., dividing the sum of the digits by 9 and noting the residue); he finds the residue for the product to be 7, for the factors to be 2 and 8. He writes down

$$\begin{array}{r} 7 \\ 8 \times 2 \\ 7 \end{array}$$

Here 8 times 2 = 16, yielding the residue 7, written above. This residue is the same as the residue of the product; hence the check is complete. It has been argued that in cases like this Rudolph used \times to indicate multiplication. This interpretation does not apply to other cases found in Rudolph's book (like the one which follows) and is wholly indefensible. We have previously seen that Rudolph used \times in the addition and subtraction of fractions. Rudolph checks the proportion $9:11=48:x$, where $x=58\frac{2}{3}$, by casting out the 7's, 9's, and 11's as follows:

$$\begin{array}{ccc} \text{"(7)} & (9) & (11)" \\ \begin{array}{r} 6 \\ 2 \times 6 \\ 6 \end{array} & \begin{array}{r} 0 \\ 0 \times 3 \\ 0 \end{array} & \begin{array}{r} 0 \\ 9 \times 4 \\ 0 \end{array} \end{array}$$

Take the check by 11's (i.e., division of a number by 11 and noting the residue). It is to be established that $9x=48$ times 11, or that 9

¹ N. Tartaglia, *op. cit.* (1556), fol. 34B.

² Chr. Rudolph, *Kunstliche Rechnung* (Augsburg, 1574 or 1588 ed.) A VIII.

times $528 = 48$ times 99. Begin by casting out the 11's of the factors 9 and 48; write down the residues 9 and 4. But the residues of 528 and 99 are both 0. Multiplying the residues 9 and 0, 4 and 0, we obtain in each case the product 0. This is shown in the figure. Note that here we do not take the product 9 times 4; hence \times could not possibly indicate 9 times 4.

The use of \times in casting out the 9's is found also in Recorde's *Ground of Artes* and in Clavius¹ who casts out the 9's and also the 7's.

Hortega² follows the Italian practice of using lines $+$, instead of \times , for the assignment of resting places for the four residues considered. Hunt³ uses the Latin cross $+$. The regular \times is used by Regius (who also casts out the 7's),⁴ Lucas,⁵ Metius,⁶ Alsted,⁷ York,⁸ Dechales,⁹ Ayres,¹⁰ and Workman.¹¹

In the more recent centuries the use of a cross in the process of casting out the 9's has been abandoned almost universally; we have found it given, however, in an English mathematical dictionary¹² of 1814 and in a twentieth-century Portuguese cyclopedia.¹³

226. *Multiplication of integers*.—In Pacioli the square of 37 is found mentally with the aid of lines indicating the digits to be multiplied together, thus:

$$\begin{array}{r} \text{"3"} \quad \times \quad \text{"7"} \\ \begin{array}{c} \downarrow \quad \downarrow \\ 3 \quad 7 \end{array} \\ \hline 1369 \end{array}$$

From the lower 7 two lines radiate, indicating 7 times 7, and 7 times 3. Similarly for the lower 3. We have here a cross as part of the line-complex. In squaring 456 a similar scheme is followed; from each digit there radiate in this case three lines. The line-complex involves three vertical lines and three well-formed crosses \times . The multiplication of 54 by 23 is explained in the manner of Pacioli by Mario Bettini¹ in 1642.

There are cases on record where the vertical lines are omitted, either as deemed superfluous or as the result of an imperfection in the typesetting. Thus an Italian writer, Unicornio,² writes:

$$\begin{array}{r} \text{"7"} \quad \text{8"} \\ \quad \times \\ 5 \quad 6 \\ \hline 4368 \end{array}$$

It would be a rash procedure to claim that we have here a use of \times to indicate the product of two numbers; these lines indicate the product of 6 and 70, and of 50 and 8; the lines are not to be taken as one symbol; they do not mean 78 times 56. The capital letter X is used by F. Ghaligai in a similar manner in his *Algebra*. The same remarks apply to J. H. Alsted³ who uses the X, but omits the vertical lines, in finding the square of 32.

A procedure resembling that of Pacioli, but with the lines marked as arrows, is found in a recent text by G. E. Crusoe.⁴

227. *Reducing radicals to radicals of the same order.*—Michael Stifel⁵ in 1544 writes: "Vt volo reducere \sqrt{z} 5 et \sqrt{c} 4 ad idem signum, sic stabit exemplum ad regulam

$$\begin{array}{r} 5 \quad 4 \\ \quad \times \\ \sqrt{z} \quad \sqrt{c} \end{array}$$

⁴ George E. Crusoe, *op. cit.*, p. 6.

⁵ Michael Stifel, *Arithmetica integra* (1544), fol. 114.

$\sqrt[3]{125}$ et $\sqrt[3]{16}$." Here $\sqrt{5}$ and $\sqrt[3]{4}$ are reduced to radicals of the same order by the use of the cross \times . The orders of the given radicals are two and three, respectively; these orders suggest the cube of 5 or 125 and the square of 4, or 16. The answer is $\sqrt[6]{125}$ and $\sqrt[6]{16}$.

Similar examples are given by Stifel in his edition of Rudolf's *Coss*,¹ Peletier,² and by De Billy.³

228. *To mark the place for "thousands."*—In old arithmetics explaining the computation upon lines (a modified abacus mode of computation), the line on which a dot signified "one thousand" was marked with a \times . The plan is as follows:

$$\begin{array}{r}
 \times \text{-----} 1000 \\
 \hspace{10em} 500 \\
 \text{-----} 100 \\
 \hspace{10em} 50 \\
 \text{-----} 50 \\
 \hspace{10em} 5 \\
 \text{-----} 1
 \end{array}$$

This notation was widely used in Continental and English texts.

229. *In place of multiplication table above 5×5 .*—This old procedure is graphically given in Recorde's *Ground of Artes* (1543?). Required to multiply 7 by 8. Write the 7 and 8 at the cross as shown here; next, $10 - 8 = 2$, $10 - 7 = 3$; write the 2 and 3 as shown:

$$\begin{array}{r}
 \begin{array}{cc}
 \text{"8"} & \text{"2"} \\
 \diagdown & \diagup \\
 7 & 3 \\
 \hline
 \end{array} \\
 56
 \end{array}$$

Then, $2 \times 3 = 6$, write the 6; $7 - 2 = 5$, write the 5. The required product is 56. We find this process again in Oronce Fine,⁴ Regius,⁵

¹ Michael Stifel, *Die Coss Christoffs Rudolffs* (Amsterdam, 1615), p. 136. (First edition, 1553.)

⁵ Hudalrich Regius, *Vtriusque arithmetices Epitome* (Strasburg, 1536), fol. 53; *ibid.* (Freiburg-in-Breisgau, 1543), fol. 56.

Stifel,¹ Boissiere,² Lucas,³ the Italian translation of Oronce Fine,⁴ the French translation of Tartaglia,⁵ Alsted,⁶ Bettini.⁷ The French edition of Tartaglia gives an interesting extension of this process, which is exhibited in the product of 996 and 998, as follows:

$$\begin{array}{r}
 996 \begin{array}{l} \text{---} \diagup \text{---} \\ \text{---} \diagdown \text{---} \end{array} 4 \\
 998 \begin{array}{l} \text{---} \diagup \text{---} \\ \text{---} \diagdown \text{---} \end{array} 2 \\
 \hline
 994 \quad 0 \quad 0 \quad 8
 \end{array}$$

230. *Amicable numbers*.—N. Chuquet⁸ shows graphically that 220 and 284 are amicable numbers (each the sum of the factors of the other) thus:

$$\begin{array}{r}
 \text{“ } 220 \qquad \qquad 284 \text{ ”} \\
 \begin{array}{r}
 110 \\
 55 \\
 44 \\
 22 \\
 20 \\
 11 \\
 10 \\
 5 \\
 4 \\
 2 \\
 1
 \end{array}
 \begin{array}{r}
 142 \\
 71 \\
 4 \\
 2 \\
 1 \\
 \hline
 220
 \end{array}
 \end{array}$$

284

The old graphic aids to computation which we have described are interesting as indicating the emphasis that was placed by early arithmeticians upon devices that appealed to the eye and thereby contributed to economy of mental effort.

231. *The St. Andrew's cross used as a symbol of multiplication*.—As already pointed out, Oughtred was the first (§ 181) to use \times as the

sign of multiplication of two numbers, as $a \times b$ (see also §§ 186, 288). The cross appears in Oughtred's *Clavis mathematicae* of 1631 and, in the form of the letter X, in E. Wright's edition of Napier's *Descriptio* (1618). Oughtred used a small symbol \times for multiplication (much smaller than the signs $+$ and $-$). In this practice he was followed by some writers, for instance, by Joseph Moxon in his *Mathematical Dictionary* (London, 1701), p. 190. It seems that some objection had been made to the use of this sign \times , for Wallis writes in a letter of September 8, 1668: "I do not understand why the sign of multiplication \times should more trouble the convenient placing of the fractions than the older signs $+$ $-$ $=$ $>$ $:$ $:$." ¹ It may be noted that Oughtred wrote the \times small and placed it high, between the factors. This practice was followed strictly by Edward Wells.²

On the other hand, in A. M. Legendre's famous textbook *Géométrie* (1794) one finds (p. 121) a conspicuously large-sized symbol \times , for multiplication. The following combination of signs was suggested by Stringham:³ Since \times means "multiplied by," and $/$ "divided by," the union of the two, viz., $\times /$, means "multiplied or divided by."

232. *Unsuccessful symbols for multiplication.*—In the seventeenth century a number of other designations of multiplication were proposed. Hérigone⁴ used a rectangle to designate the product of two factors that were separated by a comma. Thus, " $\square 5+4+3, 7 \sim 3: \sim 10$, est 38" meant $(5+4+3) \cdot (7-3) - 10 = 38$. Jones, in his *Synopsis palmariorum* (1706), page 252, uses the \equiv , the Hebrew letter *mem*, to denote a rectangular area. A six-pointed star was used by Rahn and, after him, by Brancker, in his translation of Rahn's *Teutsche Algebra* (1659). "The Sign of Multiplication is [\star] i.e., multiplied with." We encounter this use of \star in the *Philosophical Transactions*.⁵

Abraham de Graaf followed a practice, quite common among Dutch writers of the seventeenth and eighteenth centuries, of placing symbols on the right of an expression to signify direct operations (multiplication, involution), and placing the same symbols on the

⁵ *Philosophical Transactions*, Vol. XVII, (1692-94), p. 680. See also §§ 194, 547.

left of an expression to signify inverse operations. Thus, Graaf¹ multiplies x^2+4 by $2\frac{1}{4}$ by using the following symbolism:

$$\frac{x \ x \ \text{tot} \ 4}{\text{als} \ \frac{1}{4} \ x \ x \ \text{tot} \ 9} \ 2\frac{1}{4}.$$

In another place he uses this same device along with double commas, thus

$$\frac{\overline{a+b} \ , \ , \ -cc}{\overline{a+b} \ , \ , \ -ccd} d$$

to represent $(a+b)(-cc)(d) = (a+b)(-ccd)$.

Occasionally the comma was employed to mark multiplication, as in Hérigone (§ 189), F. Van Schooten,² who in 1657 gives $\frac{23,23,11,2}{3,3,3\sqrt{113,5}}$, where all the commas signify "times," as in Leibniz (§§ 197, 198, 547), in De Gua³ who writes " $3, 4, 5 \dots \&c. \ n-m-2$," in Petrus Horrebowius⁴ who lets " A,B " stand for A times B , in Abraham de Graaf⁵ who uses one or two commas, as in " $\overline{p-b},a$ " for $(p-b)a$. The German Hübsch⁶ designated multiplication by f , as in $\frac{2}{3}f\frac{1}{3}$.

233. *The dot for multiplication.*—The dot was introduced as a symbol for multiplication by G. W. Leibniz. On July 29, 1698, he wrote in a letter to John Bernoulli: "I do not like \times as a symbol for multiplication, as it is easily confounded with x ; . . . often I simply relate two quantities by an interposed dot and indicate multiplication by $ZC \cdot LM$. Hence, in designating ratio I use not one point but two points, which I use at the same time for division." It has been stated that the dot was used as a symbol for multiplication before Leibniz, that Thomas Harriot, in his *Artis analyticae praxis* (1631), used the dot in the expressions " $aaa-3 \cdot bba = +2 \cdot ccc$." Similarly, in explaining cube root, Thomas Gibson⁷ writes, in 1655, " $3 \cdot bb$," " $3 \cdot bcc$," but it

⁷ Tho. Gibson, *Syntaxis mathematica* (London, 1655), p. 36.

is doubtful whether either Harriot or Gibson meant these dots for multiplication. They are introduced without explanation. It is much more probable that these dots, which were placed after numerical coefficients, are survivals of the dots habitually used in old manuscripts and in early printed books to separate or mark off numbers appearing in the running text. Leibniz proposed the dot after he had used other symbols for over thirty years. In his first mathematical publication, the *De arte combinatoria*¹ of 1666, he used a capital letter C placed in the position \circ for multiplication, and placed in the position \cup for division. We have seen that in 1698 he advocated the point. In 1710 the Leibnizian symbols² were explained in the publication of the Berlin Academy (§ 198); multiplication is designated by apposition, and by a dot or comma (*punctum vel comma*), as in 3,2 or $a, b + c$ or $AB, CD + EF$. If at any time some additional symbol is desired, \circ is declared to be preferable to \times .

The general adoption of the dot for multiplication in Europe in the eighteenth century is due largely to Christian Wolf. It was thus used by L. Euler; it was used by James Stirling in Great Britain, where the Oughtredian \times was very popular.³ Whitworth⁴ stipulates, "The full point is used for the sign of multiplication."

234. *The St. Andrew's cross in notation for transfinite ordinal numbers.*—The notation $\omega \times 2$, with the multiplicand on the left, was chosen by G. Cantor in the place of 2ω (where ω is the first transfinite ordinal number), because in the case of three ordinal transfinite numbers, α, β, γ , the product $\alpha^\beta \cdot \alpha^\gamma$ is equal to $\alpha^{\beta+\gamma}$ when α^β is the multiplicand, but when α^γ is the multiplicand the product is $\alpha^{\gamma+\beta}$. In transfinite ordinals, $\beta + \gamma$ is not equal to $\gamma + \beta$.

SIGNS FOR DIVISION AND RATIO

235. *Early symbols.*—Hilprecht⁵ states that the Babylonians had an ideogram *IGI-GAL* for the expression of division. Aside from their fractional notation (§ 104), the Greeks had no sign for division. Diophantus⁶ separates the dividend from the divisor by the words $\epsilon\nu$

¹ G. W. Leibniz, *Opera omnia*, Vol. II (Geneva, 1768), p. 347.

⁵ H. V. Hilprecht, *The Babylonian Expedition Mathematical, etc., Tablets from the Temple Library of Nippur* (Philadelphia, 1906), p. 22.

⁶ Diophantus, *Arithmetica* (ed. P. Tannery; Leipzig, 1893), p. 286. See also G. H. F. Nesselmann, *Algebra der Griechen* (Berlin, 1842), p. 299.

μορίῳ or μορίῳ, as in the expression $\delta^{\bar{v}}\bar{\zeta}$ λείψει $\bar{\varsigma}\bar{\varsigma}$ $\bar{\kappa}\bar{\delta}$ μορίῳ $\delta^{\bar{v}}\bar{\alpha}\bar{\mu}^{\bar{\delta}}$ $\bar{\iota}\bar{\beta}$ λείψει $\bar{\varsigma}\bar{\varsigma}$, which means $(7x^2 - 24x) \div (x^2 + 12 - 7x)$. In the Bakhshālī arithmetic (§ 109) division is marked by the abbreviation *bhā* from *bhāga*, "part." The Hindus often simply wrote the divisor beneath the dividend. Similarly, they designated fractions by writing the denominator beneath the numerator (§§ 106, 109, 113). The Arabic author¹ al-Ḥaṣṣār, who belongs to the twelfth century, mentions the use of a fractional line in giving the direction: "Write the denominators below a [horizontal] line and over each of them the parts belonging to it; for example, if you are told to write three-fifths and a third of a fifth, write thus, $\frac{3}{5} \frac{1}{3}$." In a second example, four-thirteenths and

three-elevenths of a thirteenth is written $\frac{4}{13} \frac{3}{11}$. This is the first

appearance of the fractional line, known to us, unless indeed Leonardo of Pisa antedates al-Ḥaṣṣār. That the latter was influenced in this matter by Arabic authors is highly probable. In his *Liber abbaci* (1202) he uses the fractional line (§ 122). Under the caption² "De diuisionibus integrorum numerorum" he says: "Cum super quemlibet numerum quedam uirgula protracta fuerit, et super ipsam quilibet alius numerus descriptus fuerit, superior numerus partem uel partes inferioris numeri affirmat; nam inferior denominatus, et superior denominans appellatur. Vt si super binarium protracta fuerit uirgula, et super ipsam unitas descripta sit ipsa unitas unam partem de duabus partibus unius integri affirmat, hoc est medietatem sic $\frac{1}{2}$." ("When above any number a line is drawn, and above that is written any other number, the superior number stands for the part or parts of the inferior number; the inferior is called the denominator, the superior the numerator. Thus, if above the two a line is drawn, and above that unity is written, this unity stands for one part of two parts of an integer, i.e., for a half, thus $\frac{1}{2}$.")) With Leonardo, an indicated division and a fraction stand in close relation. Leonardo writes

also $\frac{1}{2} \frac{5}{6} \frac{7}{10}$, which means, as he explains, seven-tenths, and five-sixths of one-tenth, and one-half of one-sixth of one-tenth.

236. One or two lunar signs, as in 8)24 or 8)24(, which are often employed in performing long and short division, may be looked upon as symbolisms for division. The arrangement 8)24 is found in Stifel's

¹ H. Suter, *Bibliotheca mathematica* (3d ser.), Vol. II (1901), p. 24.

² *Il Liber abbaci di Leonardo Pisano* (ed. B. Boncompagni; Roma, 1857), p. 23, 24.

Arithmetica integra (1544)¹, and in W. Oughtred's different editions of his *Clavis mathematicae*. In Oughtred's *Opuscula posthuma* one finds also $\frac{A+B-C}{D}$, (§ 182). Joseph Moxon² lets $D)A+B-C$ signify our $(A+B-C) \div D$.

Perhaps the earliest to suggest a special symbol for division other than the fractional line, and the arrangement 5)15 in the process of dividing, was Michael Stifel³ in his *Deutsche Arithmetica* (1545). By the side of the symbols $+$ and $-$ he places the German capitals \mathfrak{M} and \mathfrak{D} , to signify multiplication and division, respectively. Strange to say, he did not carry out his own suggestion; neither he nor seemingly any of his German followers used the \mathfrak{M} and \mathfrak{D} in arithmetic or algebraic manipulation. The letters M and D are found again in S. Stevin, who expressed our $\frac{5x^2}{y} \cdot z^2$ in this manner:⁴

$$5\textcircled{2}D \text{ sec } \textcircled{1}M \text{ ter } \textcircled{2},$$

where *sec* and *ter* signify the "second" and "third" unknown quantity.

The inverted letter \sqsubset is used to indicate division by Gallimard,⁵ as in

$${}^{\circ}\text{"}12 \sqsubset 4=3\text{"} \text{ and } {}^{\circ}\text{"}a^2b^2 \sqsubset a^2 \text{"}.$$

In 1790 Da Cunha⁶ uses the horizontal letter \neg as a mark for division.

237. *Rahn's notation*.—In 1659 the Swiss Johann Heinrich Rahn published an algebra⁷ in which he introduced \div as a sign of division (§ 194). Many writers before him had used \div as a minus sign (§§ 164, 208). Rahn's book was translated into English by Thomas Brancker (a graduate of Exeter College, Oxford) and published, with additions from the pen of Joh. Pell, at London in 1668. Rahn's *Teutsche Algebra* was praised by Leibniz⁸ as an "elegant algebra," nevertheless it did not enjoy popularity in Switzerland and the symbol \div for division

was not adopted by his countrymen. In England, the course of events was different. The translation met with a favorable reception; Rahn's \div and some other symbols were adopted by later English writers, and came to be attributed, not to Rahn, but to John Pell. It so happened that Rahn had met Pell in Switzerland, and had received from him (as Rahn informs us) the device in the solution of equations of dividing the page into three columns and registering the successive steps in the solution. Pell and Brancker never claimed for themselves the introduction of the \div and the other symbols occurring in Rahn's book of 1569. But John Collins got the impression that not only the three-column arrangement of the page, but all the new algebraic symbols were due to Pell. In his extensive correspondence with John Wallis, Isaac Barrow, and others, Collins repeatedly spoke of \div as "Pell's symbol." There is no evidence to support this claim (§ 194).¹

The sign \div as a symbol for division was adopted by John Wallis and other English writers. It came to be adopted regularly in Great Britain and the United States, but not on the European Continent. The only text not in the English language, known to us as using it, is one published in Buenos Aires;² where it is given also in the modified form \cdot/\cdot , as in $\frac{3}{4} \cdot/\cdot \frac{5}{8} = \frac{3}{2} \frac{5}{8}$. In an American arithmetic,³ the abbreviation $\div rs$ was introduced for "divisors," and $\div nds$ for "dividends," but this suggestion met with no favor on the part of other writers.

238. *Leibniz' notations.*—In the *Dissertatio de arte combinatoria* (1668)⁴ G. W. Leibniz proposed for division the letter C, placed horizontally, thus \bigcirc , but he himself abandoned this notation and introduced the colon. His article of 1684 in the *Acta eruditorum* contains for the first time in print the colon ($:$) as the symbol for division.⁵ Leibniz says: ". . . notetur, me divisionem hic designare hoc modo: $x:y$, quod idem est ac x divis. per y seu $\frac{x}{y}$." In a publication of the year 1710⁶ we read: "According to common practice, the division

is sometimes indicated by writing the divisor beneath the dividend, with a line between them; thus a divided by b is commonly indicated by $\frac{a}{b}$; very often however it is desirable to avoid this and to continue on the same line, but with the interposition of two points; so that $a:b$ means a divided by b . But if, in the next place $a:b$ is to be divided by c , one may write $a:b:c$, or $(a:b):c$. Frankly, however, in this case the relation can be easily expressed in a different manner, namely $a:(bc)$ or $a:bc$, for the division cannot always be actually carried out but often can only be indicated and then it becomes necessary to mark the course of the deferred operation by commas or parentheses."

In Germany, Christian Wolf was influential through his textbooks in spreading the use of the colon ($:$) for division and the dot (\cdot) for multiplication. His influence extended outside Germany. A French translation of his text¹ uses the colon for division, as in " $(a-b):b$." He writes: " $a:mac = b:mbc$."

239. In Continental Europe the Leibnizian colon has been used for division and also for ratio. This symbolism has been adopted in the Latin countries with only few exceptions. In 1878 Balbontin² used in place of it the sign \div preferred by the English-speaking countries. Another Latin-American writer³ used a slanting line in this manner, $\left(\frac{6}{7} \backslash 3\right) = \frac{6:3}{7} = \frac{2}{7}$ and also $12 \backslash 3 = 4$. An author in Peru⁴

indicates division by writing the dividend and divisor on the same line, but inclosing the former in a parenthesis. Accordingly, " $(20)5$ " meant $20 \div 5$. Sometimes he uses brackets and writes the proportion $2:1\frac{1}{2} = 20:15$ in this manner: " $2:1[1]2::20:15$."

240. There are perhaps no symbols which are as completely observant of political boundaries as are \div and $:$ as symbols for division. The former belongs to Great Britain, the British dominions, and the United States. The latter belongs to Continental Europe and the Latin-American countries. There are occasional authors whose prac-

³ Felipe Senillosa, *Tratado elemental de aritmética* (nueva ed.; Buenos Aires, 1844), p. 16. We quote from p. 47: "Este signo deque hemos hecho uso en la particion (\backslash) no es usado generalmente; siendo el que se usa los dos puntos ($:$) ó la forma de quebrado. Pero un quebrado denota mas bien un cociente ó particion ejecutada que la operacion ó acto del partir; así hemos empleado este signo \backslash con analogia al del multiplicar que es éste: \times ."

⁴ Juan de Dios Salazar, *Lecciones de aritmetica* (Arequipa, 1827), p. v, 74, 89.

tices present exceptions to this general statement of boundaries, but their number is surprisingly small. Such statements would not apply to the symbolisms for the differential and integral calculus, not even for the eighteenth century. Such statements would not apply to trigonometric notations, or to the use of parentheses or to the designation of ratio and proportion, or to the signs used in geometry.

Many mathematical symbols approach somewhat to the position of world-symbols, and approximate to the rank of a mathematical world-language. To this general tendency the two signs of division \div and $:$ mark a striking exception. The only appearance of \div signifying division that we have seen on the European Continent is in an occasional translation of an English text, such as Colin Maclaurin's *Treatise of Algebra* which was brought out in French at Paris in 1753. Similarly, the only appearance of $:$ as a sign for division that we have seen in Great Britain is in a book of 1852 by T. P. Kirkman.¹ Saverien² argues against the use of more than one symbol to mark a given operation. "What is more useless and better calculated to disgust a beginner and embarrass even a geometer than the three expressions \cdot , $:$, \div , to mark division?"

241. *Relative position of divisor and dividend.*—In performing the operation of division, the divisor and quotient have been assigned various positions relative to the dividend. When the "scratch method" of division was practiced, the divisor was placed beneath the dividend and moved one step to the right every time a new figure of the quotient was to be obtained. In such cases the quotient was usually placed immediately to the right of the dividend, but sometimes, in early writers, it was placed above the dividend. In short division, the divisor was often placed to the left of the dividend, so that $a)b(c$ came to signify division.

A curious practice was followed in the Dutch journal, the *Maandelykse Mathematische Liefhebberye* (Vol. I [1759], p. 7), where $a)$ —signifies division by a , and —(a means multiplication by a . Thus:

$$\begin{array}{l} \text{" } x) \frac{xy = b - a + x}{b - a + x} \text{ " } \\ \text{ergo } y = \frac{b - a + x}{x} \end{array}$$

James Thomson called attention to the French practice of writing the divisor on the right. He remarks: "The French place the divisor

¹ T. P. Kirkman, *First Mnemonial Lessons in Geometry, Algebra and Trigonometry* (London, 1852).

² Alexandre Saverien, *Dictionnaire universel de mathématique et de physique* (Paris, 1753), "Caractere."

to the right of the dividend, and the quotient below it. . . . This mode gives the work a more compact and neat appearance, and possesses the advantage of having the figures of the quotient near the divisor, by which means the practical difficulty of multiplying the divisor by a figure placed at a distance from it is removed. . . . This method might, with much propriety, be adopted in preference to that which is employed in this country."¹

The arrangement just described is given in Bézout's arithmetic,² in the division of 14464 by 8, as follows:

$$\begin{array}{r} 14464 \overline{) 8} \\ 1808 \end{array} . "$$

242. *Order of operations in terms containing both \div and \times .*—If an arithmetical or algebraical term contains \div and \times , there is at present no agreement as to which sign shall be used first. "It is best to avoid such expressions."³ For instance, if in $24 \div 4 \times 2$ the signs are used as they occur in the order from left to right, the answer is 12; if the sign \times is used first, the answer is 3.

Some authors follow the rule that the multiplications and divisions shall be taken in the order in which they occur.⁴ Other textbook writers direct that multiplications in any order be performed first, then divisions as they occur from left to right.⁵ The term $a \div b \times b$ is interpreted by Fisher and Schwatt⁶ as $(a \div b) \times b$. An English committee⁷ recommends the use of brackets to avoid ambiguity in such cases.

243. *Critical estimates of $:$ and \div as symbols.*—D. André⁸ expresses himself as follows: "The sign $:$ is a survival of old mathematical notations; it is short and neat, but it has the fault of being symmetrical toward the right and toward the left, that is, of being a symmetrical sign of an operation that is asymmetrical. It is used less and less.

... When it is required to write the quotient of a divided by b , in the body of a statement in ordinary language, the expression $a:b$ really offers the typographical advantage of not requiring, as does $\frac{a}{b}$, a wider separation of the line in which the sign occurs from the two lines which comprehend it."

In 1923 the National Committee on Mathematical Requirements¹ voiced the following opinion: "Since neither \div nor $:$, as signs of division, plays any part in business life, it seems proper to consider only the needs of algebra, and to make more use of the fractional form and (where the meaning is clear) of the symbol $/$, and to drop the symbol \div in writing algebraic expressions."

244. *Notations for geometrical ratio.*—William Oughtred introduced in his *Clavis mathematicae* the dot as the symbol for ratio (§ 181). He wrote (§ 186) geometrical proportion thus, $a.b::c.d$. This notation for ratio and proportion was widely adopted not only in England, but also on the European Continent. Nevertheless, a new sign, the colon ($:$), made its appearance in England in 1651, only twenty years after the first publication of Oughtred's text. This colon is due to the astronomer Vincent Wing. In 1649 he published in London his *Urania practica*, which, however, exhibits no special symbolism for ratio. But his *Harmonicon coeleste* (London, 1651) contains many times Oughtred's notation $A.B::C.D$, and many times also the new notation $A:B::C:D$, the two notations being used interchangeably. Later there appeared from his pen, in London, three books in one volume, *Logistica astronomica* (1656), *Doctrina spherica* (1655), and *Doctrina theorica* (1655), each of which uses the notation $A:B::C:D$.

A second author who used the colon nearly as early as Wing was a schoolmaster who hid himself behind the initials "R.B." In his book entitled *An Idea of Arithmetik*, at first designed for the use of "the Free Schoole at Thurlow in Suffolk . . . by R.B., Schoolmaster there" (London, 1655), one finds $1.6::4.24$ and also $A:a::C:c$.

W. W. Beman pointed out in *L'Intermédiaire des mathématiciens*, Volume IX (1902), page 229, that Oughtred's Latin edition of his *Trigonometria* (1657) contains in the explanation of the use of the tables, near the end, the use of $:$ for ratio. It is highly improbable that the colon occurring in those tables was inserted by Oughtred himself.

In the *Trigonometria* proper, the colon does not occur, and Ought-

¹ *Report of the National Committee on Mathematical Requirements under the Auspices of the Mathematical Association of America, Inc. (1923), p. 81.*

red's regular notation for ratio and proportion $A.B : C.D$ is followed throughout. Moreover, in the English edition of Oughtred's trigonometry, printed in the same year (1657), but subsequent to the Latin edition, the passage of the Latin edition containing the $:$ is recast, the new notation for ratio is abandoned, and Oughtred's notation is introduced. The $:$ used to designate ratio (§ 181) in Oughtred's *Opuscula mathematica hactenus inedita* (1677) may have been introduced by the editor of the book.

It is worthy of note, also, that in a text entitled *Johnsons Arithmetik; In two Bookes* (2d ed.; London, 1633), the colon ($:$) is used to designate a fraction. Thus $\frac{3}{4}$ is written 3:4. If a fraction be considered as an indicated division, then we have here the use of $:$ for division at a period fifty-one years before Leibniz first employed it for that purpose in print. However, dissociated from the idea of a fraction, division is not designated by any symbol in Johnson's text. In dividing 8976 by 15 he writes the quotient "598 6:15."

As shown more fully elsewhere (§ 258), the colon won its way as the regular symbol for geometrical ratio, both in England and the European Continent.

245. Oughtred's dot and Wing's colon did not prevent experimentation with other characters for geometric ratio, at a later date. But none of the new characters proposed became serious rivals of the colon. Richard Balam,¹ in 1653, used the colon as a decimal separatrix, and proceeded to express ratio by turning the colon around so that the two dots became horizontal; thus "3 . . 1" meant the geometrical ratio 1 to 3. This designation was used by John Kirkby² in 1735 for arithmetical ratio; he wrote arithmetical proportion "9 . . 6 = 6 . . 3." In the algebra of John Alexander,³ of Bern, geometrical ratio is expressed by a dot, $a.b$, and also by $a::b$. Thomas York⁴ in 1687 wrote a geometrical proportion "33600 7::153600 32," using no sign at all between the terms of a ratio.

In the minds of some writers, a geometrical ratio was something more than an indicated division. The operation of division was associated with rational numbers. But a ratio may involve incommensu-

⁴ Thomas York, *Practical Treatise of Arithmetik* (London, 1687), p. 146.

rable magnitudes which are expressible by two numbers, one or both of which are irrational. Hence ratio and division could not be marked by the same symbol. Oughtred's ratio $a.b$ was not regarded by him as an indicated division, nor was it a fraction. In 1696 this matter was taken up by Samuel Jeake¹ in the following manner: "And so by some, to distinguish them [ratios] from Fractions, instead of the intervening Line, two Pricks are set; and so the Ratio Sesquialtera is thus expressed $\frac{3}{2}$." Jeake writes the geometrical proportion,

$$\frac{7}{1} \cdot \frac{9}{1} :: 7 \cdot 9."$$

Emanuel Swedenborg starts out, in his *Daedalus Hyperboreus* (Upsala, 1716), to designate geometric proportion by $: ::$, but on page 126 he introduces \div as a *signum analogicum* which is really used as a symbol for the ratio of quantities. On the European Continent one finds Hérigone² using the letter π to stand for "proportional" or ratio; he writes π where we write $:$. On the other hand, there are isolated cases where $:$ was assigned a different usage; the Italian L. Perini³ employs it as separatrix between the number of feet and of inches; his "11:4" means 11 feet 4 inches.

246. Discriminating between ratio and division, F. Schmeisser⁴ in 1817 suggested for geometric ratio the symbol $..$, which (as previously pointed out) had been used by Richard Balam, and which was employed by Thomas Dilworth⁵ in London, and in 1799 by Zachariah Jess,⁶ of Wilmington, Delaware. Schmeisser comments as follows: "At one time ratio was indicated by a point, as in $a.b$, but as this signifies multiplication, Leibniz introduced two points, as in $a:b$, a designation indicating division and therefore equally inconvenient, and current only in Germany. For that reason have Mönnich, v. Winterfeld, Krause and other thoughtful mathematicians in more recent time adopted the more appropriate designation $a..b$." Schmeisser writes (p. 233) the geometric progression: " $\div 3..6..12..24..48..96.....$ "

¹ Samuel Jeake, $\Lambda\Theta\Gamma\text{I}\Sigma\text{T}\text{I}\text{K}\text{H}\Lambda\Theta\Gamma\text{I}\text{A}$, or *Arithmetick* (London, 1696), p. 410.

⁶ Zachariah Jess, *System of Practical Surveying* (Wilmington, 1799), p. 173.

Similarly, A. E. Layng,¹ of the Stafford Grammar School in England, states: "The Algebraic method of expressing a ratio $\frac{A}{B}$ being a very convenient one, will also be found in the Examples, where it should be regarded as a symbol for the words *the ratio of A to B*, and not as implying the operation of division; it should not be used for book-work."

247. *Division in the algebra of complex numbers.*—As, in the algebra of complex numbers, multiplication is in general not commutative, one has two cases in division, one requiring the solution of $a = bx$, the other the solution of $a = yb$. The solution of $a = bx$ is designated by Peirce² $\frac{a}{b \times}$, by Schröder³ $\frac{a}{b}$, by Study⁴ and Cartan $\frac{a}{b}$.

The solution of $a = yb$ is designated by Peirce $\frac{a}{\times b}$ and by Schröder $a : b$, by Study and Cartan $\frac{a}{.b}$. The \times and the $.$ indicate in this notation the place of the unknown factor. Study and Cartan use also the notations of Peirce and Schröder.

SIGNS OF PROPORTION

248. *Arithmetical and geometrical progression.*—The notation $\div\div$ was used by W. Oughtred (§ 181) to indicate that the numbers following were in continued geometrical proportion. Thus, $\div\div 2, 6, 18, 54, 162$ are in continued geometric proportion. During the seventeenth and eighteenth centuries this symbol found extensive application; beginning with the nineteenth century the need of it gradually passed away, except among the Spanish-American writers. Among the many English writers using $\div\div$ are John Wallis,⁵ Richard Sault⁶, Edward Cocker,⁷ John Kersey,⁸ William Whiston,⁹ Alexander Mal-

colm,¹ Sir Jonas Moore,² and John Wilson.³ Colin Maclaurin indicates in his *Algebra* (1748) a geometric progression thus: " $\ddot{\div} 1:q:q^2:q^3:q^4:q^5$: etc." E. Bézout⁴ and L. Despiau⁵ write for arithmetical progression " $\div 1.3.5.7.9$," and " $\ddot{\div} 3:6:12$ " for geometrical progression.

Symbols for arithmetic progression were less common than for geometric progression, and they were more varied. Oughtred had no symbol. Wallis⁶ denotes an arithmetic progression $A, B, C, D \ddot{\div}$, or by $a, b, c, d, e, f \ddot{\div}$. The sign \div , which we cited as occurring in Bézout and Despiau, is listed by Saverien⁷ who writes " $\div 1.2.3.4.5$, etc." But Saverien gives also the six dots $:::$, which occur in Stone⁸ and Wilson.⁹ A still different designation, $\ddot{\div}$, for arithmetical progression is due to Kirkby¹⁰ and Emerson,¹¹ another $\ddot{\div}$ to Clark,¹² again another $\ddot{\div}$ is found in Blassière.¹³ Among French writers using \div for arithmetic progression and $\ddot{\div}$ for geometric progression are Lamy,¹⁴ De Belidor,¹⁵ Suzanne,¹⁶ and Fournier;¹⁷ among Spanish-American

writers using these two symbols are Senillosa,¹ Izquierdo,² Liévano,³ and Porfirio da Motta Pegado.⁴ In German publications \div for arithmetical progression and $\ddot{\div}$ for geometric progression occur less frequently than among the French. In the 1710 publication in the *Miscellanea Berolinensia*⁵ $\ddot{\div}$ is mentioned in a discourse on symbols (§ 198). The $\ddot{\div}$ was used in 1716 by Emanuel Swedenborg.⁶

Emerson⁷ designated harmonic progression by the symbol $\ddot{\div}$ and harmonic proportion by $\ddot{\vdots}$.

249. *Arithmetical proportion* finds crude symbolic representation in the *Arithmetic* of Boethius as printed at Augsburg in 1488 (see Figure 103). Being, in importance, subordinate to geometrical proportion, the need of a symbolism was less apparent. But in the seventeenth century definite notations came into vogue. William Oughtred appears to have designed a symbolism. Oughtred's language (*Clavis* [1652], p. 21) is "Ut 7.4:12.9 vel 7.7—3:12.12—3. Arithmeticè proportionales sunt." As later in his work he does not use arithmetical proportion in symbolic analysis, it is not easy to decide whether the symbols just quoted were intended by Oughtred as part of his algebraic symbolism or merely as punctuation marks in ordinary writing. John Newton⁸ says: "As 8,5:6,3. Here 8 exceeds 5, as much as 6 exceeds 3."

Wallis⁹ says: "Et pariter 5,3; 11,9; 17,15; 19,17. sunt in eadem progressionē arithmetica." In P. Chelucci's¹⁰ *Institutiones analyticae*, arithmetical proportion is indicated thus: 6.8 ∴ 10.12. Oughtred's notation is followed in the article "Caractère" of the *Encyclopédie*

méthodique (*Mathématiques*) (Paris: Liège, 1784). Lamy¹ says: "Proportion arithmétique, 5,7 :: 10,12.c'est à dire qu'il y a même différence entre 5 et 7, qu'entre 10 et 12."

In Arnould's geometry² the same symbols are used for arithmetical progression as for geometrical progression, as in $7.3 :: 13.9$ and $6.2 :: 12.4$.

Samuel Jeake (1696)³ speaks of "∴ Three Pricks or Points, sometimes in disjunct proportion for the words *is as*."

A notation for arithmetical proportion, noticed in two English seventeenth-century texts, consists of five dots, thus ::; Richard Balam⁴ speaks of "arithmetical disjunct proportionals" and writes " $2.4 :: 3.5$ "; Sir Jonas Moore⁵ uses :: and speaks of "disjunct proportionals." Balam adds, "They may also be noted thus, $2...4 = 3...5$." Similarly, John Kirkby⁶ designated arithmetical proportion in this manner, $9..6 = 6..3$, the symbolism for arithmetical ratio being $8..2$. L'Abbé Deidier (1739)⁷ adopts $20.2 ∴ 78.60$. Before that Weigel⁸ wrote "(o) $3| ∴ 4.7$ " and "(o) $2.| ∴ 3.5$." Wolff (1710),⁹ Panchaud,¹⁰ Saverien,¹¹ L'Abbé Foucher,¹² Emerson,¹³ place

the three dots as did Chelucci and Deidier, viz., $a.b \cdot \cdot c.d$. Cosalli¹ writes the arithmetical proportion $a:b \cdot \cdot c:d$. Later Wolff² wrote $a-b = c-d$.

Blassière³ prefers $2:7 \div 10:15$. Juan Gerard⁴ transfers Oughtred's signs for geometrical proportion to arithmetical proportion and writes accordingly, $9.7 :: 5.3$. In French, Spanish, and Latin-American texts Oughtred's notation, $8.6:5.3$, for arithmetical proportion has persisted. Thus one finds it in Benito Bails,⁵ in a French text for the military,⁶ in Fournier,⁷ in Gabriel Izquierdo,⁸ in Indalecio Liévano.⁹

250. *Geometrical proportion*.—A presentation of geometrical proportion that is not essentially rhetorical is found in the Hindu Bakhshālī arithmetic, where the proportion $10:1\frac{6}{10} = 4:1\frac{6}{10}$ is written in the form¹⁰

10	163	4	pha 163
1	60	1	150

It was shown previously (§ 124) that the Arab al-Qalasādī (fifteenth century) expresses the proportion $7.12 = 84:144$ in this manner: $144 :: 84 :: 12 :: 7$. Regiomontanus in a letter writes our modern $a:b:c$ in the form $a.b.c$, the dots being simply signs of separation.¹¹ In the edition of the *Arithmetica* of Boethius, published at Augsburg in 1488, a crude representation of geometrical and arithmetical propor-

FIG. 103.—From the *Arithmetica* of Boethius, as printed in 1488, the last two pages. (Taken from D. F. Smith's *Rara arithmetica* [Boston, 1898], p. 28.)

1487) is shown in Figure 39. Stifel, in his edition of Rudolff's *Coss* (1553), uses vertical lines of separation, as in

$$“100 \mid \frac{1}{2} z \mid 100 z \mid \text{Facit } \frac{1}{2} zz.”$$

Tartaglia¹ indicates a proportion thus:

$$“\text{Se } £ 3 // \text{ val } \beta 4 // \text{ che valeranno } £ 28.”$$

Chr. Clavius² writes:

$$“9 . 126 . 5 . ? \text{ fiunt } 70 .”$$

¹ N. Tartaglia, *La prima parte del General Tratato di Numeri, etc.* (Venice 1556), fol. 129B.

² Chr. Clavius, *Epitome arithmeticae practicae* (Rome, 1583), p. 137.

This notation is found as late as 1699 in Corachan's arithmetic¹ in such statements as

$$\begin{array}{c} "A . B . C . D . \\ 5 . 7 . 15 . 21 . " \end{array}$$

Schwenter² marks the geometric proportion 68—51—85, then finds the product of the means $51 \times 85 = 4335$ and divides this by 68. In a work of Galileo,³ in 1635, one finds:

$$\begin{array}{r} \text{"Regula aurea} \\ 58\text{---}95996.\text{---}21600. \\ 21600 \\ \hline 57597600 \\ 95996 \\ 191992 \\ \hline 58 \left| \begin{array}{c} 357 \\ 20735 \\ 3339 \\ 42 \end{array} \right| 13600 \end{array}$$

In other places in Galileo's book the three terms in the proportion are not separated by horizontal lines, but by dots or simply by spacing. Johan Stampioen,⁴ in 1639, indicates our $a:b=b:c$ by the symbolism:

$$"a,, b \text{ gel} : b ,, c."$$

Further illustrations are given in § 221.

These examples show that some mode of presenting to the eye the numbers involved in a geometric proportion, or in the application of the rule of three, had made itself felt soon after books on mathematics came to be manufactured. Sometimes the exposition was rhetorical, short words being available for the writing of proportion. As late as 1601 Philip Lansberg⁵ wrote "ut 5 ad 10; ita 10 ad 20," meaning

¹ Ivan Baptista Corachan, *Arithmetica demonstrada* (Valencia, 1699), p. 199.

⁵ Philip Lansberg, *Triangulorum geometriae libri quatuor* (Middelburg [Zee-land], 1663), p. 5.

$5:10=10:20$. Even later the Italian Cardinal Michelangelo Ricci¹ wrote “esto AC ad CB , ut 9 ad 6.” If the fourth term was not given, but was to be computed from the first three, the place for the fourth term was frequently left vacant, or it was designated by a question mark.

251. *Oughtred's notation*.—As the symbolism of algebra was being developed and the science came to be used more extensively, the need for more precise symbolism became apparent. It has been shown (§ 181) that the earliest noted symbolism was introduced by Oughtred. In his *Clavis mathematicae* (London, 1631) he introduced the notation $5.10::6.12$ which he retained in the later editions of this text, as well as in his *Circles of Proportion* (1632, 1633, 1660), and in his *Trigonometria* (1657).

As previously stated (§ 169) the suggestion for this symbolism may have come to Oughtred from the reading of John Dee's Introduction to Billingley's *Euclid* (1570). Probably no mathematical symbol has been in such great demand in mathematics as the dot. It could be used, conveniently, in a dozen or more different meanings. But the avoidance of confusion necessitates the restriction of its use. Where then shall it be used, and where must other symbols be chosen? Oughtred used the dot to designate ratio. That made it impossible for him to follow John Napier in using the dot as the separatrix in decimal fractions. Oughtred could not employ two dots ($:$) for ratio, because the two dots were already pre-empted by him for the designation of aggregation, $:A+B$: signifying $(A+B)$. Oughtred reserved the dot for the writing of ratio, and used four dots to separate the two equal ratios. The four dots were an unfortunate selection. The sign of equality ($=$) would have been far superior. But Oughtred adhered to his notation. Editions of his books containing it appeared repeatedly in the seventeenth century. Few symbols have met with more prompt adoption than those of Oughtred for proportion. Evidently the time was ripe for the introduction of a definite unambiguous symbolism. To be sure the adoption was not immediate. Nineteen years elapsed before another author used the notation $A.B::C.D$. In 1650 John Kersey brought out in London an edition of Edmund Wingate's *Arithmetique made easie*, in which this notation is used. After this date, the publications employing it became frequent, some of them being the productions of pupils of Oughtred. We have

¹ *Michaelis Angeli Riccii exercitatio geometrica de maximis et minimis* (London, 1668), p. 3.

seen it in Vincent Wing,¹ Seth Ward,² John Wallis,³ in "R.B.," a schoolmaster in Suffolk,⁴ Samuel Foster,⁵ Sir Jonas Moore,⁶ and Isaac Barrow.⁷ John Wallis⁸ sometimes uses a peculiar combination of processes, involving the simplification of terms, during the very act of writing proportion, as in " $\frac{3}{2}A = 4A \cdot \frac{3}{2}A = 3A :: \frac{3}{2}A = 2A \cdot \frac{3}{2}A :: 8.6 :: 4.3$." Here the dot signifies ratio.

The use of the dot, as introduced by Oughtred, did not become universal even in England. As early as 1651 the astronomer, Vincent Wing (§ 244), in his *Harmonicon Coeleste* (London), introduced the colon (:) as the symbol for ratio. This book uses, in fact, both notations for ratio. Many times one finds $A.B::C.D$ and many times $A:B::C:D$. It may be that the typesetter used whichever notation happened at the moment to strike his fancy. Later, Wing published three books (§ 244) in which the colon (:) is used regularly in writing ratios. In 1655 another writer, "R.B.," whom we have cited as using the symbols $A.B::C.D$, employed in the same publication also $A:B::C:D$. The colon was adopted in 1661 by Thomas Streete.⁹

That Oughtred himself at any time voluntarily used the colon as the sign for ratio does not appear. In the editions of his *Clavis* of 1648 and 1694, the use of : to signify ratio has been found to occur only once in each copy (§ 186); hence one is inclined to look upon this notation in these copies as printer's errors.

252. *Struggle in England between Oughtred's and Wing's notations, before 1700.*—During the second half of the seventeenth century there was in England competition between (.) and (:) as the symbols for the designation of the ratio (§§ 181, 251). At that time the dot maintained its ascendancy. Not only was it used by the two most influ-

ential English mathematicians before Newton, namely, John Wallis and Isaac Barrow, but also by David Gregory,¹ John Craig,² N. Mercator,³ and Thomas Brancker.⁴ I. Newton, in his letter to Oldenburg of October 24, 1676,⁵ used the notation $. :: .$, but in Newton's *De analysi per aequationes terminorum infinitas*, the colon is employed to designate ratio, also in his *Quadratura curvarum*.

Among seventeenth-century English writers using the colon to mark ratio are James Gregory,⁶ John Collins,⁷ Christopher Wren,⁸ William Leybourn,⁹ William Sanders,¹⁰ John Hawkins,¹¹ Joseph Raphson,¹² E. Wells,¹³ and John Ward.¹⁴

253. *Struggle in England between Oughtred's and Wing's notations during 1700-1750*.—In the early part of the eighteenth century, the dot still held its place in many English books, but the colon gained in ascendancy, and in the latter part of the century won out. The single dot was used in John Alexander's *Algebra* (in which proportion is written in the form $a.b :: c.X$ and also in the form $a \cdots b : c \cdots X$)¹⁵ and, in John Colson's translation of Agnesi (before 1760).¹⁶ It was used

by John Wilson¹ and by the editors of Newton's *Universal arithmetick*.² In John Harris' *Lexicon technicum* (1704) the dot is used in some articles, the colon in others, but in Harris' translation³ of G. Pardies' geometry the dot only is used. George Shelley⁴ and Hatton⁵ used the dot.

254. *Sporadic notations*.—Before the English notations $. :: .$ and $: :: :$ were introduced on the European Continent, a symbolism consisting of vertical lines, a modification of Tartaglia's mode of writing, was used by a few continental writers. It never attained popularity, yet maintained itself for about a century. René Descartes (1619–21)⁶ appears to have been the first to introduce such a notation $a|b||c|d$. In a letter⁷ of 1638 he replaces the middle double stroke by a single one. Slusius⁸ uses single vertical lines in designating four numbers in geometrical proportion, $p|a|e|d-a$. With Slusius, two vertical strokes $||$ signify equality. Jaques de Billy⁹ marks five quantities in continued proportion, thus $3-B5|B5-1|2|B5+1|3+B5$, where B means "square root." In reviewing publications of Huygens and others, the original notation of Descartes is used in the *Journal des Sçavans* (Amsterdam)¹⁰ for the years 1701, 1713, 1716. Likewise, Picard,¹¹ De la Hire,¹² Abraham de Graaf,¹³ and Parent¹⁴ use the notation $a|b||xx|ab$.

¹² De la Hire, *Nouveaux elemens des sections coniques* (Paris, 1701), p. 184. J. Tropfke refers to the edition of 1679, p. 184.

¹³ Abraham de Graaf, *De vervulling van der geometria en algebra* (Amsterdam, 1708), p. 97.

¹⁴ A. Parent, *Essais et recherches de mathématique et de physique* (Paris, 1713), p. 224.

It is mentioned in the article "Caractere" in Diderot's *Encyclopédie* (1754). La Hire writes also " $aa||xx||ab$ " for $a^2:x^2=x^2:ab$.

On a subject of such universal application in commercial as well as scientific publications as that of ratio and proportion, one may expect to encounter occasional sporadic attempts to alter the symbolism. Thus Hérigone¹ writes " $hg \pi ga 2|2 hb \pi bd$, signifi. HG est ad GA , ut HB ad BD ," or, in modern notation, $hg:ga=hb:bd$; here $2|2$ signifies equality, π signifies ratio. Again Peter Mengol,² of Bologna, writes " $a;r:a2;ar$ " for $a:r=a^2:ar$. The London edition of the algebra of the Swiss J. Alexander³ gives the signs $..::$ but uses more often designations like $b \dashv a : d \left| \frac{ad}{b} \right.$. Ade Mercastel,⁴ of Rouen, writes $2,,3;;8,,12$. A

close approach to the marginal symbolism of John Dee is that of the Spaniard Zaragoza⁵ $4.3:12.9$. More profuse in the use of dots is J. Kresa⁶ who writes $x...r::r... \frac{rr}{x}$, also $AE...EF::AD...DG$. The latter form is adopted by the Spaniard Cassany⁷ who writes $128...119::3876$; it is found in two American texts,⁸ of 1797.

In greater conformity with pre-Oughtredian notations is van Schooten's notation⁹ of 1657 when he simply separates the three given numbers by two horizontal dashes and leaves the place for the unknown number blank. Using Stevin's designation for decimal fractions, he writes "65—^{lb.} 95,^{flor.} 753^{lb.} ③—1." Abraham de Graaf¹⁰ is

partial to the form $2-4=6-12$. Thomas York¹ uses three dashes 125—429—10—?, but later in his book writes “33600 7 :: 153600 32,” the ratio being here indicated by a blank space. To distinguish ratios from fractions, Samuel Jeake² states that by some authors “instead of the intervening Line, two Pricks are set; and so the *Ratio sesquialtera* is thus expressed $\frac{3}{2} \cdot$.” Accordingly, Jeake writes “ $\frac{1}{7} \cdot \frac{1}{9}$:: 9.7.”

In practical works on computation with logarithms, and in some arithmetics a rhetorical and vertical arrangement of the terms of a proportion is found. Mark Forster³ writes:

“As Sine of 40 deg.	9,8080675
To 1286	3,1092401
So is Radius	10,0000000
To the greatest Random 2000	3,3011726
Or, For Random at 36 deg.”	

As late as 1789 Benjamin Workman⁴ writes “ $\begin{array}{c} \text{lb. d. lb.} \\ 1-7-112 \end{array} \cdot$ ”

255. *Oughtred's notation on the European Continent.*—On the European Continent the dot as a symbol of geometrical ratio, and the four dots of proportion, $\cdot :: \cdot$, were, of course, introduced later than in England. They were used by Dulaurens,⁵ Prestet,⁶ Varignon,⁷ Pardies,⁸ De l'Hospital,⁹ Jakob Bernoulli,¹⁰ Johann Bernoulli,¹¹ Carré,¹² Her-

to be used in the Continent later than in England, and it was also later to disappear on the Continent.

256. An unusual departure in the notation for geometric proportion which involved an excellent idea was suggested by a Dutch author, Johan Stampioen,¹ as early as the year 1639. This was only eight years after Oughtred had proposed his $. :: .$ Stampioen uses the designation $A, , B = C, , D$. We have noticed, nearly a century later, the use of two commas to represent ratio, in a French writer, Mercastel. But the striking feature with Stampioen is the use of Recorde's sign of equality in writing proportion. Stampioen anticipates Leibniz over half a century in using $=$ to express the equality of two ratios. He is also the earliest writer that we have seen on the European Continent to adopt Recorde's symbol in writing ordinary equations. He was the earliest writer after Descartes to use the exponential form a^3 . But his use of $=$ did not find early followers. He was an opponent of Descartes whose influence in Holland at that time was great. The employment of $=$ in writing proportion appears again with James Gregory² in 1668, but he found no followers in this practice in Great Britain.

257. *Slight modifications of Oughtred's notation.*—A slight modification of Oughtred's notation, in which commas took the place of the dots in designating geometrical ratios, thus $A, B : : C, D$, is occasionally encountered both in England and on the Continent. Thus Sturm³ writes " $3b, 2b :: 2b, \frac{4bb}{3b}$ sive $\frac{4b}{3}$," Lamy⁴ " $3, 6 :: 4, 8$," as did also Ozanam,⁵ De Moivre,⁶ David Gregory,⁷ L'Abbé Deidier,⁸ Belidor,⁹ who also uses the regular Oughtredian signs, Maria G. Agnesi,¹⁰

Nicolaas Ypey,¹ and Manfredi.² This use of the comma for ratio, rather than the Oughtredian dot, does not seem to be due to any special cause, other than the general tendency observable also in the notation for decimal fractions, for writers to use the dot and comma more or less interchangeably.

An odd designation occurs in an English edition of Ozanam,³ namely, "*A.2.B.3::C.4.D.6*," where *A, B, C, D* are quantities in geometrical proportion and the numbers are thrown in by way of concrete illustration.

258. *The notation : :: in Europe and America.*—The colon which replaced the dot as the symbol for ratio was slow in making its appearance on the Continent. It took this symbol about half a century to cross the British Channel. Introduced in England by Vincent Wing in 1651, its invasion of the Continent hardly began before the beginning of the eighteenth century. We find the notation *A:B::C:D* used by Leibniz,⁴ Johann Bernoulli,⁵ De la Hire,⁶ Parent,⁷ Bomic,⁸ Saulmon,⁹ Swedenborg,¹⁰ Lagny,¹¹ Senès,¹² Chevalier de Louville,¹³ Clairaut,¹⁴ Bouguer,¹⁵ Nicole (1737, who in 1715 had used *. :: .*),¹⁶ La

Caille,¹ D'Alembert,² Vicenti Riccati,³ and Jean Bernoulli.⁴ In the Latin edition of De la Caille's⁵ *Lectiones* four notations are explained, namely, $3.12::2.8$, $3:12::2:8$, $3:12=2:8$, $3|12||2|8$, but the notation $3:12::2:8$ is the one actually adopted.

The notation $: ::$ was commonly used in England and the United States until the beginning of the twentieth century, and even now in those countries has not fully surrendered its place to $= : .$ As late as 1921 $: ::$ retains its place in Edwards' *Trigonometry*,⁶ and it occurs in even later publications. The $: ::$ gained full ascendancy in Spain and Portugal, and in the Latin-American countries. Thus it was used in Madrid by Juan Gerard,⁷ in Lisbon by Joao Felix Pereira⁸ and Luiz Porfirio da Motta Pegado,⁹ in Rio de Janeiro in Brazil by Francisco Miguel Pires¹⁰ and C. B. Ottoni,¹¹ at Lima in Peru by Maximo Vazquez¹² and Luis Monsante,¹³ at Buenos Ayres by Florentino Garcia,¹⁴ at Santiago de Chile by Gabriel Izquierdo,¹⁵ at Bogota in Colombia by Indalecio Liévano,¹⁶ at Mexico by Juan Maria Balbontin.¹⁷

¹⁷ Juan Maria Balbontin, *Tratado elemental de aritmetica* (Mexico, 1878), p. 96.

259. *The notation of Leibniz.*—In the second half of the eighteenth century this notation, $A:B::C:D$, had gained complete ascendancy over $A.B::C.D$ in nearly all parts of Continental Europe, but at that very time it itself encountered a serious rival in the superior Leibnizian notation, $A:B=C:D$. If a proportion expresses the equality of ratios, why should the regular accepted equality sign not be thus extended in its application? This extension of the sign of equality—to writing proportions had already been made by Stampioen (§ 256). Leibniz introduced the colon ($:$) for ratio and for division in the *Acta eruditorum* of 1684, page 470 (§ 537). In 1693 Leibniz expressed his disapproval of the use of special symbols for ratio and proportion, for the simple reason that the signs for division and equality are quite sufficient. He¹ says: “Many indicate by $a \div b \div\div c \div d$ that the ratios a to b and c to d are alike. But I have always disapproved of the fact that special signs are used in ratio and proportion, on the ground that for ratio the sign of division suffices and likewise for proportion the sign of equality suffices. Accordingly, I write the ratio a to b thus: $a:b$ or $\frac{a}{b}$ just as is done in dividing a by b . I designate proportion, or the equality of two ratios by the equality of the two divisions or fractions. Thus when I express that the ratio a to b is the same as that of c to d , it is sufficient to write $a:b=c:d$ or $\frac{a}{b}=\frac{c}{d}$.”

Cogent as these reasons are, more than a century passed before his symbolism for ratio and proportion triumphed over its rivals.

Leibniz's notation, $a:b=c:d$, is used in the *Acta eruditorum* of 1708, page 271. In that volume (p. 271) is laid the editorial policy that in algebra the Leibnizian symbols shall be used in the *Acta*. We quote the following relating to division and proportion (§ 197): “We shall designate division by two dots, unless circumstance should prompt adherence to the common practice. Thus, we shall have $a:b=\frac{a}{b}$. Hence with us there will be no need of special symbols for denoting proportion. For instance, if a is to b as c is to d , we have $a:b=c:d$.”

The earliest influential textbook writer who adopted Leibniz' notation was Christian Wolf. As previously seen (§ 255) he sometimes

¹ G. W. Leibniz, *Matheseos universalis pars prior*, de Terminis incomplexis, No. 16; reprinted in *Gesammelte Werke* (C. I. Gerhardt), 3. Folge, II³, Band VII (Halle, 1863), p. 56.

wrote $a.b=c.d$. In 1710¹ he used both $3.12::5.20$ and $3:12=5:20$, but from 1713² on, the Leibnizian notation is used exclusively.

One of the early appearances of $a:b=c:d$ in France is in Clairaut's algebra³ and in Saverien's dictionary,⁴ where Saverien argues that the equality of ratios is best indicated by $=$ and that $::$ is superfluous. It is found in the publications of the Paris Academy for the year 1765,⁵ in connection with Euler who as early as 1727 had used it in the commentaries of the Petrograd Academy.

Benjamin Panchaud brought out a text in Switzerland in 1743,⁶ using $:=$. In the Netherlands⁷ it appeared in 1763 and again in 1775.⁸ A mixture of Oughtred's symbol for ratio and the $=$ is seen in Pieter Venema⁹ who writes $.=$.

In Vienna, Paulus Mako¹⁰ used Leibniz' notation both for geometric and arithmetic proportion. The Italian Petro Giannini¹¹ used $=:$ for geometric proportion, as does also Paul Frisi.¹² The first volume of *Acta Helvetia*¹³ gives this symbolism. In Ireland, Joseph Fenn¹⁴ used it about 1770. A French edition of Thomas Simpson's geometry¹⁵ uses $:=$. Nicolas Fuss¹⁶ employed it in St. Petersburg. In England,

John Cole¹ adopted it in 1812, but a century passed after this date before it became popular there.

The Leibnizian notation was generally adopted in Europe during the nineteenth century.

In the United States the notation $: :: :$ was the prevailing one during the nineteenth century. The Leibnizian signs appeared only in a few works, such as the geometries of William Chauvenet² and Benjamin Peirce.³ It is in the twentieth century that the notation $: = :$ came to be generally adopted in the United States.

A special symbol for variation sometimes encountered in English and American texts is \propto , introduced by Emerson.⁴ "To the Common Algebraic Characters already receiv'd I add this \propto , which signifies a general Proportion; thus, $A \propto \frac{BC}{D}$, signifies that A is in a constant ratio to $\frac{BC}{D}$." The sign was adopted by Chrystal,⁵ Castle,⁶ and others.

SIGNS OF EQUALITY

260. *Early symbols.*—A symbol signifying "it gives" and ranking practically as a mark for equality is found in the linear equation of the Egyptian Ahmes papyrus (§ 23, Fig. 7). We have seen (§ 103) that Diophantus had a regular sign for equality, that the contraction *pha* answered that purpose in the Bakhshālī arithmetic (§ 109), that the Arab al-Qalasādi used a sign (§ 124), that the dash was used for the expression of equality by Regiomontanus (§ 126), Pacioli (§ 138), and that sometimes Cardan (§ 140) left a blank space where we would place a sign of equality.

261. *Recorde's sign of equality.*—In the printed books before Recorde, equality was usually expressed rhetorically by such words as *aequales*, *aequantur*, *esgale*, *faciunt*, *ghelijck*, or *gleich*, and sometimes by the abbreviated form *aeq*. Prominent among the authors expressing equality in some such manner are Kepler, Galileo, Torricelli, Cavalieri, Pascal, Napier, Briggs, Gregory St. Vincent, Tacquet, and Fermat. Thus, about one hundred years after Recorde, some of

¹ John Cole, *Stereogoniometry* (London, 1812), p. 44, 265.

² William Chauvenet, *Treatise on Elementary Geometry* (Philadelphia, 1872), p. 69.

⁵ G. Chrystal, *Algebra*, Part I, p. 275.

⁶ Frank Castle, *Practical Mathematics for Beginners* (London, 1905), p. 317.

the most noted mathematicians used no symbol whatever for the expression of equality. This is the more surprising if we remember that about a century before Recorde, Regiomontanus (§ 126) in his correspondence had sometimes used for equality a horizontal dash —, that the dash had been employed also by Pacioli (§ 138) and Ghaligai (§ 139). Equally surprising is the fact that apparently about the time of Recorde a mathematician at Bologna should independently originate the same symbol (Fig. 53) and use it in his manuscripts.

Recorde's =, after its début in 1557, did not again appear in print until 1618, or sixty-one years later. That some writers used symbols in their private manuscripts which they did not exhibit in their printed books is evident, not only from the practice of Regiomontanus, but also from that of John Napier who used Recorde's = in an algebraic manuscript which he did not publish and which was first printed in 1839.¹ In 1618 we find the = in an anonymous Appendix (very probably due to Oughtred) printed in Edward Wright's English translation of Napier's famous *Descriptio*. But it was in 1631 that it received more than general recognition in England by being adopted as the symbol for equality in three influential works, Thomas Harriot's *Artis analyticae praxis*, William Oughtred's *Clavis mathematicae*, and Richard Norwood's *Trigonometria*.

262. *Different meanings of =.*—As a source of real danger to Recorde's sign was the confusion of symbols which was threatened on the European Continent by the use of = to designate relations other than that of equality. In 1591 Francis Vieta in his *In artem analyticen isagoge* used = to designate arithmetical difference (§ 177). This designation was adopted by Girard (§ 164), by Sieur de Var-Lezard² in a translation of Vieta's *Isagoge* from the Latin into French, De Graaf,³ and by Franciscus à Schooten⁴ in his edition of Descartes' *Géométrie*. Descartes⁵ in 1638 used = to designate *plus ou moins*, i.e., \pm .

Another complication arose from the employment of = by Johann

Caramuel¹ as the separatrix in decimal fractions; with him $102 = 857$ meant our 102.857. As late as 1706 G. H. Paricius² used the signs $=$, $:$, and $-$ as general signs to separate numbers occurring in the process of solving arithmetical problems. The confusion of algebraic language was further increased when Dulaurens³ and Reyher⁴ designated parallel lines by $=$. Thus the symbol $=$ acquired five different meanings among different continental writers. For this reason it was in danger of being discarded altogether in favor of some symbol which did not labor under such a handicap.

263. *Competing symbols*.—A still greater source of danger to our $=$ arose from competing symbols. Pretenders sprang up early on both the Continent and in England. In 1559, or two years after the appearance of Recorde's algebra, the French monk, J. Buteo,⁵ published his *Logistica* in which there appear equations like " $1A, \frac{1}{3}B, \frac{1}{3}C$ [14" and " $3A.3B.15C$ [120," which in modern notation are $x + \frac{1}{3}y + \frac{1}{3}z = 14$ and $3x + 3y + 15z = 120$. Buteo's $[$ functions as a sign of equality. In 1571, a German writer, Wilhelm Holzmann, better known under the name of Xylander, brought out an edition of Diophantus' *Arithmetica*⁶ in which two parallel vertical lines $||$ were used for equality. He gives no clue to the origin of the symbol. Moritz Cantor⁷ suggests that perhaps the Greek word *ισοι* ("equal") was abbreviated in the manuscript used by Xylander, by the writing of only the two letters ι . Weight is given to this suggestion in a Parisian manuscript on Diophantus where a single ι denoted equality.⁸ In 1613, the Italian writer Giovanni Camillo Glorioso used Xylander's two vertical lines for equality.⁹ It was used again by the Cardinal Michaelangelo Ricci.¹⁰ This character was adopted by a few Dutch and French

mathematicians during the hundred years that followed, especially in the writing of proportion. Thus, R. Descartes,¹ in his *Opusculs de 1619-1621*, made the statement, "ex progressionem 1|2||4|8||16|32|| habentur numeri perfecti 6, 28, 496." Pierre de Carcavi, of Lyons, in a letter to Descartes (Sept. 24, 1649), writes the equation "+1296-3060a+2664a²-1115a³+239a⁴-25a⁵+a⁶||0," where "la lettre a est l'inconnue en la maniere de Monsieur Vieta" and || is the sign of equality.² De Monconys³ used it in 1666; De Sluse⁴ in 1668 writes our $be=a^2$ in this manner " $be || aa$." De la Hire (§ 254) in 1701 wrote the proportion $a:b=x^2:ab$ thus: " $a|b||xx|ab$." This symbolism is adopted by the Dutch Abraham de Graaf⁵ in 1703, by the Frenchman Parent⁶ in 1713, and by certain other writers in the *Journal des Sçavans*.⁷ Though used by occasional writers for more than a century, this mark || never gave promise of becoming a universal symbol for equality. A single vertical line was used for equality by S. Reyher in 1698. With him, " $A|B$ " meant $A=B$. He attributes⁸ this notation to the Dutch orientalist and astronomer Jacob Golius, saying: "Especially indebted am I to Mr. Golio for the clear algebraic mode of demonstration with the sign of equality, namely the rectilinear stroke standing vertically between two magnitudes of equal measure."

In England it was Leonard and Thomas Digges, father and son, who introduced new symbols, including a line complex \propto for equality (Fig. 78).⁹

The greatest oddity was produced by Hérigone in his *Cursus mathematicus* (Paris, 1644; 1st ed., 1634). It was the symbol " $2|2$." Based on the same idea is his " $3|2$ " for "greater than," and his " $2|3$ " for "less than." Thus, $a^2+ab=b^2$ is indicated in his symbolism by

⁹ Thomas Digges, *Stratoticos* (1590), p. 35.

" $a2+ba2|2b2$." Though clever and curious, this notation did not appeal. In some cases Hérigone used also \sqsubset to express equality. If this sign is turned over, from top to bottom, we have the one used by F. Dulaurens¹ in 1667, namely, \sqsupset ; with Dulaurens \sqsupset signifies "majus," \sqsubset signifies "minus"; Leibniz, in some of his correspondence and unpublished papers, used² \sqsubset and also³ $=$; on one occasion he used the Cartesian⁴ \approx for identity. But in papers which he printed, only the sign $=$ occurs for equality.

Different yet was the equality sign \mathfrak{J} used by J. V. Andrea⁵ in 1614.

The substitutes advanced by Xylander, Andrea, the two Digges, Dulaurens, and Hérigone at no time seriously threatened to bring about the rejection of Recorde's symbol. The real competitor was the mark \approx , prominently introduced by René Descartes in his *Géométrie* (Leyden, 1637), though first used by him at an earlier date.⁶

264. *Descartes' sign of equality*.—It has been stated that the sign was suggested by the appearance of the combined *ae* in the word *aequalis*, meaning "equal." The symbol has been described by Cantor⁷ as the union of the two letters *ae*. Better, perhaps, is the description given by Wieleitner⁸ who calls it a union of *oe* reversed; his minute examination of the symbol as it occurs in the 1637 edition of the *Géométrie* revealed that not all of the parts of the letter *e* in the combination *oe* are retained, that a more accurate way of describing that symbol is to say that it is made up of two letters *o*, that is, *oo* pressed against each other and the left part of the first excised. In some of the later appearances of the symbol, as given, for example, by van Schooten in 1659, the letter *e* in *oe*, reversed, remains intact. We incline to the opinion that Descartes' symbol for equality, as it appears in his *Géométrie* of 1637, is simply the astronomical symbol

for Taurus, placed sideways, with the opening turned to the left. This symbol occurs regularly in astronomical works and was therefore available in some of the printing offices.

Descartes does not mention Recorde's notation; his *Géométrie* is void of all bibliographical and historical references. But we know that he had seen Harriot's *Praxis*, where the symbol is employed regularly. In fact, Descartes himself¹ used the sign = for equality in a letter of 1640, where he wrote " $1C - 6N = 40$ " for $x^3 - 6x = 40$. Descartes does not give any reason for advancing his new symbol \propto . We surmise that Vieta's, Girard's, and De Var-Lezard's use of = to denote arithmetical "difference" operated against his adoption of Recorde's sign. Several forces conspired to add momentum to Descartes' symbol \propto . In the first place, the *Géométrie*, in which it first appeared in print, came to be recognized as a work of genius, giving to the world analytic geometry, and therefore challenging the attention of mathematicians. In the second place, in this book Descartes had perfected the exponential notation, a^n (n , a positive integer), which in itself marked a tremendous advance in symbolic algebra; Descartes' \propto was likely to follow in the wake of the exponential notation. The \propto was used by F. Debeaune² as early as October 10, 1638, in a letter to Roberval.

As Descartes had lived in Holland several years before the appearance of his *Géométrie*, it is not surprising that Dutch writers should be the first to adopt widely the new notation. Van Schooten used the Cartesian sign of equality in 1646.³ He used it again in his translation of Descartes' *Géométrie* into Latin (1649), and also in the editions of 1659 and 1695. In 1657 van Schooten employed it in a third publication.⁴ Still more influential was Christiaan Huygens⁵ who used \propto as early as 1646 and in his subsequent writings. He persisted in this usage, notwithstanding his familiarity with Recorde's symbol through the letters he received from Wallis and Brouncker, in which it occurs many times.⁶ The Descartian sign occurs in the writings of Hudde and De Witt, printed in van Schooten's 1659 and later editions of Descartes' *Géométrie*. Thus, in Holland, the symbol was adopted by

the most influential mathematicians of the seventeenth century. It worked its way into more elementary textbooks. Jean Prestet¹ adopted it in his *Nouveaux Éléments*, published at Paris in 1689. This fact is the more remarkable, as in 1675 he² had used the sign $=$. It seems to indicate that soon after 1675 the sign \propto was gaining over $=$ in France. Ozanam used \propto in his *Dictionnaire mathématique* (Amsterdam, 1691), though in other books of about the same period he used \sim , as we see later. The Cartesian sign occurs in a French text by Bernard Lamy.³

In 1659 Descartes' equality symbol invaded England, appearing in the Latin passages of Samuel Foster's *Miscellanies*. Many of the Latin passages in that volume are given also in English translation. In the English version the sign $=$ is used. Another London publication employing Descartes' sign of equality was the Latin translation of the algebra of the Swiss Johann Alexander.⁴ Michael Rolle uses \propto in his *Traité d'algèbre* of 1690, but changes to $=$ in 1709.⁵ In Holland, Descartes' equality sign was adopted in 1660 by Kinckhvyzen,⁶ in 1694 by De Graaf,⁷ except in writing proportions, when he uses $=$. Bernard Nieuwentiit uses Descartes' symbol in his *Considerationes* of 1694 and 1696, but preferred $=$ in his *Analysis infinitorum* of 1695. De la Hire⁸ in 1701 used the Cartesian character, as did also Jacob Bernoulli in his *Ars Conjectandi* (Basel, 1713). Descartes' sign of equality was widely used in France and Holland during the latter part of the seventeenth and the early part of the eighteenth centuries, but it never attained a substantial foothold in other countries.

265. *Variations in the form of Descartes' symbol.*—Certain variations of Descartes' symbol of equality, which appeared in a few texts, are probably due to the particular kind of symbols available or improvable in certain printing establishments. Thus Johaan Cara-

mucl¹ in 1670 employed the symbol \mathcal{E} ; the 1679 edition of Fermat's² works gives ∞ in the treatise *Ad locos planos et solidos isagoge*, but in Fermat's original manuscripts this character is not found.³ On the margins of the pages of the 1679 edition occur also expressions of which " $DA\{BE$ " is an example, where $DA=BE$. J. Ozanam⁴ employs \sim in 1682 and again in 1693; he refers to \sqsubset as used to mark equality, "mais nous le changerons en celuy-cy, ∞ ; que nous semble plus propre, et plus naturel." Andreas Spole⁵ said in 1692: " \sim vel = est nota aequalitates." Wolff⁶ gives the Cartesian symbol inverted, thus α .

266. *Struggle for supremacy*.—In the seventeenth century, Recorde's = gained complete ascendancy in England. We have seen its great rival \propto in only two books printed in England. After Harriot and Oughtred, Recorde's symbol was used by John Wallis, Isaac Barrow, and Isaac Newton. No doubt these great names helped the symbol on its way into Europe.

On the European Continent the sign = made no substantial headway until 1650 or 1660, or about a hundred years after the appearance of Recorde's algebra. When it did acquire a foothold there, it experienced sharp competition with other symbols for half a century before it fully established itself. The beginning of the eighteenth century may be designated roughly as the time when all competition of other symbols practically ceased. Descartes himself used = in a letter of September 30, 1640, to Mersenne. A Dutch algebra of 1639 and a tract of 1640, both by J. Stampioen,⁷ and the *Teutsche Algebra* of the Swiss Johann Heinrich Rahn (1659), are the first continental textbooks that we have seen which use the symbol. Rahn says, p. 18: "Bey disem anlaasz habe ich das namhafte gleichzeichen = zum ersten gebraucht, bedeutet ist gleich, $2a=4$ heisset $2a$ ist gleich 4." It was used by Bernhard Frenicle de Bessy, of magic-squares fame, in a

letter¹ to John Wallis of December 20, 1661, and by Huips² in the same year. Leibniz, who had read Barrow's *Euclid* of 1655, adopted the Recordean symbol, in his *De arte combinatoria* of 1666 (§ 545), but then abandoned it for nearly twenty years. The earliest textbook brought out in Paris that we have seen using this sign is that of Arnauld³ in 1667; the earliest in Leyden is that of C. F. M. Dechales⁴ in 1674.

The sign = was used by Prestet,⁵ Abbé Catelan and Tschirnhaus,⁶ Hoste,⁷ Ozanam,⁸ Nieuwentijt,⁹ Weigel,¹⁰ De Lagny,¹¹ Carré,¹² L'Hospital,¹³ Polynier,¹⁴ Guisnée,¹⁵ and Reyneau.¹⁶

This list constitutes an imposing array of names, yet the majority of writers of the seventeenth century on the Continent either used Descartes' notation for equality or none at all.

267. With the opening of the eighteenth century the sign = gained rapidly; James Bernoulli's *Ars Conjectandi* (1713), a posthumous publication, stands alone among mathematical works of prominence of that late date, using \propto . The dominating mathematical advance of the time was the invention of the differential and integral calculus. The fact that both Newton and Leibniz used Recorde's symbol led to its general adoption. Had Leibniz favored Descartes'

\propto , then Germany and the rest of Europe would probably have joined France and the Netherlands in the use of it, and Recorde's symbol would probably have been superseded in England by that of Descartes at the time when the calculus notation of Leibniz displaced that of Newton in England. The final victory of $=$ over \propto seems mainly due to the influence of Leibniz during the critical period at the close of the seventeenth century.

The sign of equality $=$ ranks among the very few mathematical symbols that have met with universal adoption. Recorde proposed no other algebraic symbol; but this one was so admirably chosen that it survived all competitors. Such universality stands out the more prominently when we remember that at the present time there is still considerable diversity of usage in the group of symbols for the differential and integral calculus, for trigonometry, vector analysis, in fact, for every branch of mathematics.

The difficulty of securing uniformity of notation is further illustrated by the performance of Peter van Musschenbroek,¹ of Leyden, an eighteenth-century author of a two-volume text on physics, widely known in its day. In some places he uses $=$ for equality and in others for ratio; letting *S. s.* be distances, and *T. t.* times, he says: "Erit *S. s.* :: *T. t.* exprimunt hoc Mathematici scribendo, est $S = T$. sive Spatium est uti tempus, nam signum $=$ non exprimit aequalitatem, sed rationem." In writing proportions, the ratio is indicated sometimes by a dot, and sometimes by a comma. In 1754, Musschenbroek had used \propto for equality.²

268. *Variations in the form of Recorde's symbol.*—There has been considerable diversity in the form of the sign of equality. Recorde drew the two lines very long (Fig. 71) and close to each other, \equiv . This form is found in Thomas Harriot's algebra (1631), and occasionally in later works, as, for instance, in a paper of De Lagny³ and in Schwab's edition of Euclid's *Data*.⁴ Other writers draw the two lines very short, as does Weigel⁵ in 1693. At Upsala, Emanuel

¹ Petro van Musschenbroek, *Introductio ad philosophiam naturalem*, Vol. I (Leyden, 1762), p. 75, 126.

² Petri van Musschenbroek, *Dissertatio physica experimentalis de magnele* (Vienna), p. 239.

⁴ Johann Christoph Schwab, *Euclids Data* (Stuttgart, 1780), p. 7.

⁵ Erhardi Weigeli *Philosophia mathematica* (Jena, 1693), p. 181.

Swedenborg¹ makes them very short and slanting upward, thus \approx . At times one encounters lines of moderate length, drawn far apart \approx , as in an article by Nicole² and in other articles, in the *Journal des Sçavans*. Frequently the type used in printing the symbol is the figure 1, placed horizontally, thus³ \approx or \approx .

In an American arithmetic⁵ occurs, " $1+6, =7, \times 6=42, \div 2=21$."

Wolfgang Bolyai⁶ in 1832 uses \doteq to signify absolute equality; \approx , equality in content; $A(=B \text{ or } B=)A$, to signify that each value of A is equal to some value of B ; $A(=)B$, that each of the values of A is equal to some value of B , and vice versa.

To mark the equality of vectors, Bellavitis⁷ used in 1832 and later the sign \simeq .

Some recent authors have found it expedient to assign $=$ a more general meaning. For example, Stolz and Gmeiner⁸ in their theoretical arithmetic write $a \circ b = c$ and read it " a mit b ist c ," the $=$ signifying "is explained by" or "is associated with." The small circle placed between a and b means, in general, any relation or *Verknüpfung*.

De Morgan⁹ used in one of his articles on logarithmic theory a double sign of equality $= =$ in expressions like $(be^{\beta} \sqrt{-1})^x = ne^{\nu} \sqrt{-1}$, where β and ν are angles made by b and n , respectively, with the initial line. He uses this double sign to indicate "that every symbol shall express not merely the length and direction of a line, but also the quantity of revolution by which a line, setting out from the unit line, is supposed to attain that direction."

⁹ A. de Morgan, *Trans. Cambridge Philos. Society*, Vol. VII (1842), p. 186.

269. *Variations in the manner of using it.*—A rather unusual use of equality signs is found in a work of Deidier¹ in 1740, viz.,

$$\frac{0+1+2}{2+2+2} = \frac{3}{6} = \frac{1}{2}; \quad \frac{0.1.4.}{4,4,4,} = \frac{5}{12} = \frac{1}{3} + \frac{1}{12}.$$

H. Vitalis² uses a modified symbol: “Nota \simeq significat repetitam aequationem *vt* $10 \simeq 6. \vdash 4 \simeq 8 \vdash 2.$ ” A discrimination between $=$ and ∞ is made by Gallimard³ and a few other writers; “ $=$, est égale à; ∞ qui signifie tout simplement, égal à, ou, qui est égal à.”

A curious use, in the same expressions, of $=$, the comma, and the word *aequalis* is found in a Tacquet-Whiston⁴ edition of Euclid, where one reads, for example, “erit $8 \times 432 = 3456$ aequalis $8 \times 400 = 3200$, $+8 \times 30 = 240$, $+8 \times 2 = 16.$ ”

L. Gustave du Pasquier⁵ in discussing general complex numbers employs the sign of double equality \equiv to signify “equal by definition.”

The relations between the coefficients of the powers of x in a series may be expressed by a formal equality involving the series as a whole, as in

$$1 + n_{(1)}x + n_{(2)}x^2 + \dots \stackrel{f}{=} (1+x)\{1 + (n+1)_{(1)}x + (n-1)_{(2)}x^2 + \dots,$$

where the symbol $\stackrel{f}{=}$ indicates that the equality is only formal, not arithmetical.⁶

270. *Nearly equal.*—Among the many uses made in recent years of the sign \sim is that of “nearly equal to,” as in “ $e \sim \frac{1}{4}$ ”; similarly, $e \simeq \frac{1}{4}$ is allowed to stand for “equal or nearly equal to.”⁷ A. Eucken⁸ lets $\underline{\simeq}$ stand for the lower limit, as in “ $J \underline{\simeq} 45.10^{-40}$ (untere Grenze),” where J means a mean moment of inertia. Greenhill⁹ denotes approximate

equality by \approx . An early suggestion due to Fischer¹ was the sign \simeq for "approximately equal to." This and three other symbols were proposed by Boon² who designed also four symbols for "greater than but approximately equal to" and four symbols for "less than but approximately equal to."

SIGNS OF COMMON FRACTIONS

271. *Early forms.*—In the Egyptian Ahmes papyrus unit fractions were indicated by writing a special mark over the denominator (§§ 22, 23). Unit fractions are not infrequently encountered among the Greeks (§ 41), the Hindus and Arabs, in Leonardo of Pisa (§ 122), and in writers of the later Middle Ages in Europe.³ In the text *Trisatika*, written by the Hindu Śrīdhara, one finds examples like the following: "How much money is there when half a *kākini*, one-third of this and one-fifth of this are added together?"

Statement	<table><tr><td>1</td><td>1</td></tr><tr><td>1</td><td>2</td></tr></table>	1	1	1	2	<table><tr><td>1</td><td>1</td><td>1</td></tr><tr><td>1</td><td>2</td><td>3</td></tr></table>	1	1	1	1	2	3	<table><tr><td>1</td><td>1</td><td>1</td><td>1</td></tr><tr><td>1</td><td>2</td><td>3</td><td>5</td></tr></table>	1	1	1	1	1	2	3	5	Answer. <i>Varātikas</i> 14."
1	1																					
1	2																					
1	1	1																				
1	2	3																				
1	1	1	1																			
1	2	3	5																			

This means $1 \times \frac{1}{2} + 1 \times \frac{1}{2} \times \frac{1}{3} + 1 \times \frac{1}{2} \times \frac{1}{3} \times \frac{1}{5} = \frac{7}{6}$, and since 20 *varātikas* = 1 *kākini*, the answer is 14 *varātikas*.

John of Meurs (early fourteenth century)⁴ gives $\frac{7}{6}$ as the sum of three unit fractions $\frac{1}{2}$, $\frac{1}{3}$, and $\frac{1}{6}$, but writes " $\frac{1}{2} \frac{1}{3} \frac{1}{6}$," which is an ascending continued fraction. He employs a slightly different notation for $\frac{1}{24}$, namely, " $\frac{1}{4} \frac{1}{3} \circ \frac{1}{2} \circ$."

Among Heron of Alexandria and some other Greek writers the numerator of any fraction was written with an accent attached, and was followed by the denominator marked with two accents (§ 41). In some old manuscripts of Diophantus the denominator is placed above the numerator (§ 104), and among the Byzantines the denominator is found in the position of a modern exponent;⁵ ϑ^a signified accordingly $\frac{1}{11}$.

⁵ F. Hultsch, *Metrologicorum scriptorum reliquiae*, Vol. I (Leipzig, 1864), p. 173–75.

The Hindus wrote the denominator beneath the numerator, but without a separating line (§§ 106, 109, 113, 235).

In the so-called arithmetic of John of Seville,¹ of the twelfth century (?), which is a Latin elaboration of the arithmetic of al-Khowârizmî, as also in a tract of Alnasavi (1030 A.D.),² the Indian mode of writing fractions is followed; in the case of a mixed number, the fractional part appears below the integral part. Alnasavi pursues this course consistently³ by writing a zero when there is no integral part; for example, he writes $\frac{1}{11}$ thus: $\frac{0}{11}$.

272. The fractional line is referred to by the Arabic writer al-Ḥaṣṣâr (§§ 122, 235, Vol. II § 422), and was regularly used by Leonardo of Pisa (§§ 122, 235). The fractional line is absent in a twelfth-century Munich manuscript;⁴ it was not used in the thirteenth-century writings of Jordanus Nemorarius,⁵ nor in the *Gernardus algorithmus demonstratus*, edited by Joh. Schöner (Nürnberg, 1534), Part II, chapter i.⁶ When numerator and denominator of a fraction are letters, Gernardus usually adopted the form ab (a numerator, b denominator), probably for graphic reasons. The fractional line is absent in the Bamberger arithmetic of 1483, but occurs in Widman (1489), and in a fifteenth-century manuscript at Vienna.⁷ While the fractional line came into general use in the sixteenth century, instances of its omission occur as late as the seventeenth century.

273. Among the sixteenth- and seventeenth-century writers omitting the fractional line were Baëza⁸ in an arithmetic published at Paris, Dibvadius⁹ of Denmark, and Paolo Casati.¹⁰ The line is

usually omitted in the writings of Marin Mersenne¹ of 1644 and 1647. It is frequently but not usually omitted by Tobias Beutel.²

In the middle of a fourteenth-century manuscript³ one finds the notation $3 \overline{5}$ for $\frac{3}{5}$, $4 \overline{7}$ for $\frac{4}{7}$. A Latin manuscript,⁴ Paris 7377A, which is a translation from the Arabic of Abu Kamil, contains the fractional line, as in $\frac{1}{9}$, but $\frac{1}{9}-\frac{1}{9}$ is a continued fraction and stands for $\frac{1}{9}$ plus $\frac{1}{81}$, whereas $\frac{5}{9}-\frac{1}{2}$ as well as $\frac{9}{9}\frac{1}{2}$ represent simply $\frac{1}{18}$. Similarly, Leonardo of Pisa,⁵ who drew extensively from the Arabic of Abu Kamil, lets $\frac{5}{8}\frac{6}{8}$ stand for $\frac{5}{8}\frac{6}{4}$, there being a difference in the order of reading. Leonardo read from right to left, as did the Arabs, while authors of Latin manuscripts of about the fourteenth century read as we do from left to right. In the case of a mixed number, like $3\frac{1}{2}$, Leonardo and the Arabs placed the integer to the right of the fraction.

274. *Special symbols for simple fractions* of frequent occurrence are found. The Ahmes papyrus has special signs for $\frac{1}{2}$ and $\frac{2}{3}$ (§ 22); there existed a hieratic symbol for $\frac{1}{4}$ (§ 18). Diophantus employed special signs for $\frac{1}{2}$ and $\frac{2}{3}$ (§ 104). A notation to indicate one-half, almost identical with one sometimes used during the Middle Ages in connection with Roman numerals, is found in the fifteenth century with the Arabic numerals. Says Cappelli: "I remark that for the designation of one-half there was used also in connection with the Arabic numerals, in the XV. century, a line between two points, as $4 \div$ for $4\frac{1}{2}$, or a small cross to the right of the number in place of an exponent, as 4^{\dagger} , presumably a degeneration of $1/1$, for in that century this form was used also, as $7 \ 1/1$ for $7\frac{1}{2}$. Toward the close of the XV. century one finds also often the modern form $\frac{1}{2}$."⁶ The Roman designation of certain unit fractions are set forth in § 58. The peculiar designations employed in the Austrian cask measures are found in § 89. In a fifteenth-century manuscript we find: "Whan pou hayst write pat, for pat pat leues, write such a merke as is here ^w vpon his hede, pe quych

⁶ A. Cappelli, *Lexicon Abbreviaturarum* (Leipzig, 1901), p. L.

merke schal betoken halfe of pe odde pat was take away";¹ for example, half of 241 is 120^o. In a mathematical roll written apparently in the south of England at the time of Recorde, or earlier, the character \sim stands for one-half, a dot \cdot for one-fourth, and \simeq for three-fourths.² In some English archives³ of the sixteenth and seventeenth centuries one finds one-half written in the form $\frac{1}{2}$. In the earliest arithmetic printed in America, the *Arte para aprender todo el menor del arithmetica* of Pedro Paz (Mexico, 1623), the symbol \underline{o} is used for $\frac{1}{2}$ a few times in the early part of the book. This symbol is taken from the *Arithmetica practica* of the noted Spanish writer, Juan Perez de Moya, 1562 (14th ed., 1784, p. 13), who uses \underline{o} and also $\frac{o}{m}$ for $\frac{1}{2}$ or *medio*.

This may be a convenient place to refer to the origin of the sign % for "per cent," which has been traced from the study of manuscripts by D. E. Smith.⁴ He says that in an Italian manuscript an "unknown writer of about 1425 uses a symbol which, by natural stages, developed into our present %. Instead of writing 'per 100', 'P 100' or 'P cento,' as had commonly been done before him, he wrote 'P $\frac{100}{100}$ ' for 'P $\frac{1}{100}$,' just as the Italians wrote $\frac{1}{2}$, $\frac{2}{3}$, ... and 1° , 2° , ... for primo, secundo, etc. In the manuscripts which I have examined the evolution is easily traced, the $\frac{100}{100}$ becoming $\frac{1}{100}$ about 1650, the original meaning having even then been lost. Of late the 'per' has been dropped; leaving only $\frac{1}{100}$ or %." By analogy to %, which is now made up of two zeros, there has been introduced the sign $\frac{1}{1000}$, having as many zeros as 1,000 and signifying *per mille*.⁵ Cantor represents the fraction $(100+p)/100$ "by the sign 1, 0p, not to be justified mathematically but in practice extremely convenient."

275. *The solidus*.⁶—The ordinary mode of writing fractions $\frac{a}{b}$ is typographically objectionable as requiring three terraces of type. An effort to remove this objection was the introduction of the solidus, as in a/b , where all three fractional parts occur in the regular line of type. It was recommended by De Morgan in his article on "The Calculus

¹ R. Steele, *The Earliest Arithmetics in English* (London, 1922), p. 17, 19. The *p* in "pou," "pat," etc., appears to be our modern *th*.

⁵ Moritz Cantor, *Politische Arithmetik* (2. Aufl.; Leipzig, 1903), p. 4.

⁶ The word "solidus" in the time of the Roman emperors meant a gold coin (a "solid" piece of money); the sign / comes from the old form of the initial letter *s*, namely, *ſ*, just as £ is the initial of *libra* ("pound"), and *d* of *denarius* ("penny").

of Functions," published in the *Encyclopaedia Metropolitana* (1845). But practically that notation occurs earlier in Spanish America. In the *Gazetas de Mexico* (1784), page 1, Manuel Antonio Valdes used a curved line resembling the sign of integration, thus $1/4$, $3/4$; Henri Cambuston¹ brought out in 1843, at Monterey, California, a small arithmetic employing a curved line in writing fractions. The straight solidus is employed, in 1852, by the Spaniard Antonio Serra Y Oliveres.² In England, De Morgan's suggestion was adopted by Stokes³ in 1880. Cayley wrote Stokes, "I think the 'solidus' looks very well indeed . . . ; it would give you a strong claim to be President of a Society for the Prevention of Cruelty to Printers." The solidus is used frequently by Stolz and Gmeiner.⁴

While De Morgan recommended the solidus in 1843, he used $a:b$ in his subsequent works, and as Glaisher remarks, "answers the purpose completely and it is free from the objection to \div viz., that the pen must be twice removed from the paper in the course of writing it."⁵ The colon was used frequently by Leibniz in writing fractions (§ 543, 552) and sometimes also by Karsten,⁶ as in $1:3 = \frac{1}{3}$; the \div was used sometimes by Cayley.

G. Peano adopted the notation b/a whenever it seemed convenient.⁷

Alexander Macfarlane⁸ adds that Stokes wished the solidus to take the place of the horizontal bar, and accordingly proposed that the terms immediately preceding and following be welded into one, the welding action to be arrested by a period. For example, $m^2 - n^2/m^2 + n^2$ was to mean $(m^2 - n^2)/(m^2 + n^2)$, and a/bcd to mean $\frac{a}{bcd}$, but $a/bc \cdot d$ to mean $\frac{a}{bc} d$. "This solidus notation for algebraic expressions oc-

curring in the text has since been used in the *Encyclopaedia Britannica*, in Wiedemann's *Annalen* and quite generally in mathematical literature." It was recommended in 1915 by the Council of the London Mathematical Society to be used in the current text.

"The use of small fractions in the midst of letterpress," says Bryan,¹ "is often open to the objection that such fractions are difficult to read, and, moreover, very often do not come out clearly in printing. It is especially difficult to distinguish $\frac{1}{3}$ from $\frac{1}{8}$ For this reason it would be better to confine the use of these fractions to such common forms as $\frac{1}{4}$, $\frac{1}{2}$, $\frac{3}{4}$, $\frac{1}{3}$, and to use the notation 18/22 for other fractions."

SIGNS OF DECIMAL FRACTIONS

276. *Stevin's notation*.—The invention of decimal fractions is usually ascribed to the Belgian Simon Stevin, in his *La Disme*, published in 1585 (§ 162). But at an earlier date several other writers came so close to this invention, and at a later date other writers advanced the same ideas, more or less independently, that rival candidates for the honor of invention were bound to be advanced. The *La Disme* of Stevin marked a full grasp of the nature and importance of decimal fractions, but labored under the burden of a clumsy notation. The work did not produce any immediate effect. It was translated into English by R. Norton² in 1608, who slightly modified the notation by replacing the circles by round parentheses. The fraction .3759 is given by Norton in the form $3^{(1)}7^{(2)}5^{(3)}9^{(4)}$.

277. Among writers who adopted Stevin's decimal notation is Wilhelm von Kalchheim³ who writes 693 ② for our 6.93. He applies it also to mark the decimal subdivisions of linear measure: "Die Zeichen sind diese: ① ist ein ganzes oder eine ruthe: ② ist ein erstes / prime oder schuh: ③ ist ein zweites / secunde oder Zoll: ④ ein drittes / korn oder gran: ⑤ ist ein viertes stipflin oder minuten: und so forthan." Before this J. H. Beyer writes⁴ $8\overset{v}{798}$ for 8.00798; also

¹ G. H. Bryan, *Mathematical Gazette*, Vol. VIII (1917), p. 220.

² *Disme: the Art of Tenths, or Decimall Arithmetike*, . . . invented by the excellent mathematician, Simon Stevin. Published in English with some additions by Robert Norton, Gent. (London, 1608). See also A. de Morgan in *Companion to the British Almanac* (1851), p. 11.

³ *Zusammenfassung ellicher geometrischen Aufgaben*. . . . Durch Wilhelm von Kalchheim, genant Lohausen Obristen (Bremen, 1629), p. 117.

⁴ Johann Hartmann Beyer, *Logistica decimalis, das ist die Kunstrechnung mit den zehntheligen Brüchen* (Frankfurt a/M., 1603). We have not seen Beyer's

14.3761^{viii} for 14.00003761, 123.4⁰.5ⁱ.9ⁱⁱ.8ⁱⁱⁱ.7^{iv}.2^v. or 123.4ⁱ.5ⁱⁱ.9ⁱⁱⁱ.8^{iv}.7^v.2^{vi} or 123. 459. 872 for 123.459872, 643 for 0.0643.

That Stevin's notation was not readily abandoned for a simpler one is evident from Ozanam's use¹ of a slight modification of it as late as 1691, in passages like "^{(1) (2) (3) (4)} $\frac{6667}{10000}$ ég. d 6 6 6 7," and ^{(0) (1) (2)} 3 9 8 for our 3.98.

278. *Other notations used before 1617.*—Early notations which one might be tempted to look upon as decimal notations appear in works whose authors had no real comprehension of decimal fractions and their importance. Thus Regiomontanus,² in dividing 85869387 by 60000, marks off the last four digits in the dividend and then divides by 6 as follows:

$$\begin{array}{r} 8\ 5\ 8\ 6\ |\ 9\ 3\ 8\ 7 \\ 1\ 4\ 3\ 1 \end{array}$$

In the same way, Pietro Borgi³ in 1484 uses the stroke in dividing 123456 by 300, thus

$$\begin{array}{r} \text{"per 300} \\ 1\ 2\ 3\ 4\ |\ 5\ 6 \\ 4\ 1\ 1\ \text{---} \\ 4\ 1\ 1\ \frac{56}{100} \text{"} \end{array}$$

Francesco Pellos (Pellizzati) in 1492, in an arithmetic published at Turin, used a point and came near the invention of decimal fractions.⁴

Christoff Rudolff⁵ in his *Coss* of 1525 divides 652 by 10. His words are: "Zu exempel / ich teile 652 durch 10. stet also 65/2. ist 65 der quocient vnnd 2 das übrig. Kompt aber ein Zal durch 100 zu teilen / schneid ab die ersten zwo figuren / durch 1000 die ersten drey / also weiter für yede o ein figur." ("For example, I divide 652 by 10. It gives 65/2; thus, 65 is the quotient and 2 the remainder. If a number is to be divided by 100, cut off the first two figures, if by

book; our information is drawn from J. Tropfke, *Geschichte der Elementar-Mathematik*, Vol. I (2d ed.; Berlin and Leipzig, 1921), p. 143; S. Günther, *Geschichte der Mathematik*, Vol. I (Leipzig, 1908), p. 342.

⁴ D. E. Smith, *Rara arithmetica* (1898), p. 50, 52.

⁵ Quoted by J. Tropfke, *op. cit.*, Vol. I (2d ed., 1921), p. 140.

1,000 the first three, and so on for each 0 a figure.") This rule for division by 10,000, etc., is given also by P. Apian¹ in 1527.

In the *Exempel Büchlin* (Vienna, 1530), Rudolff performs a multiplication involving what we now would interpret as being decimal fractions.² Rudolff computes the values $375 (1 + \frac{5}{10})^n$ for $n = 1, 2, \dots, 10$. For $n = 1$ he writes $393 \mid 75$, which really denotes 393.75; for $n = 3$ he writes $434 \mid 109375$. The computation for $n = 4$ is as follows:

$$\begin{array}{r} 4 \ 3 \ 4 \mid 1 \ 0 \ 9 \ 3 \ 7 \ 5 \\ 2 \ 1 \ 7 \ 0 \ 5 \ 4 \ 6 \ 8 \ 7 \ 5 \\ 4 \ 5 \ 5 \mid 8 \ 1 \ 4 \ 8 \ 4 \ 3 \ 7 \ 5 \end{array}$$

Here Rudolff uses the vertical stroke as we use the comma and, in passing, uses decimals without appreciating the importance and generality of his procedure.

F. Vieta fully comprehends decimal fractions and speaks of the advantages which they afford;³ he approaches close to the modern notations, for, after having used (p. 15) for the fractional part smaller type than for the integral part, he separated the decimal from the integral part by a vertical stroke (p. 64, 65); from the vertical stroke to the actual comma there is no great change.

In 1592 Thomas Masterson made a close approach to decimal fractions by using a vertical bar as separatrix when dividing £337652643 by a million and reducing the result to shillings and pence. He wrote:⁴

$$\text{“} \begin{array}{l} \text{facit} \left\{ \begin{array}{l} l. \quad 3 \ 3 \ 7 \mid 6 \ 5 \ 2 \ 6 \ 4 \ 3 \text{”} \\ s. \quad 1 \ 3 \mid 0 \ 5 \ 2 \ 8 \ 6 \ 0 \\ d. \quad \text{—} \mid 6 \ 3 \ 4 \ 3 \ 2 \ 0 \end{array} \right. \end{array}$$

John Kepler in his *Oesterreichisches Wein-Visier-Büchlein* (Lintz, MDCXVI), reprinted in Kepler's *Opera omnia* (ed. Ch. Frisch), Volume V (1864), page 547, says: “Fürs ander, weil ich kurtze Zahlen brauche, derohalben es oft Brüche geben wirdt, so mercke, dass alle Ziffer, welche nach dem Zeichen (C) folgen, die gehören zu

divided on the question as to whether or not Pitiscus used the decimal point, the majority of them stating that he did use it. This disagreement arises from the fact that some writers, apparently not having access to the 1608 or 1612 edition of the *Trigonometria*¹ of Pitiscus, reason from insufficient data drawn from indirect sources, while others fail to carry conviction by stating their conclusions without citing the underlying data.

Two queries are involved in this discussion: (1) Did Pitiscus employ decimal fractions in his writings? (2) If he did employ them, did he use the dot as the separatrix between units and tenths?

Did Pitiscus employ decimal fractions? As we have seen, the need of considering this question arises from the fact that some early writers used a symbol of separation which we could interpret as separating units from tenths, but which they themselves did not so interpret. For instance,² Christoff Rudolff in his *Coss* of 1525 divides 652 by 10, "stet also 65|2. ist 65 der quocient vnnnd 2 das übrig." The figure 2 looks like two-tenths, but in Rudolff's mind it is only a remainder. With him the vertical bar served to separate the 65 from this remainder; it was not a decimal separatrix, and he did not have the full concept of decimal fractions. Pitiscus, on the other hand, did have this concept, as we proceed to show. In computing the chord of an arc of 30° (the circle having 10⁷ for its radius), Pitiscus makes the statement (p. 44): "All these chords are less than the radius and as it were certain parts of the radius, which parts are commonly written $\frac{5176381}{10000000}$. But much more brief and necessary for the work, is this writing of it .05176381. For those numbers are altogether of the same value, as these two numbers 09. and $\frac{9}{10}$ are." In the original Latin the last part reads as follows: "... quae partes vulgo sic scriberentur $\frac{5176381}{10000000}$. Sed multò compendiosior et ad calculum accommodatior est ista scriptio .05176381. Omnino autem idem isti numeri valent, sicut hi duo numeri 09. et $\frac{9}{10}$ idem valent."

One has here two decimals. The first is written .05176381. The dot on the left is not separating units from tenths; it is only a rhetorical mark. The second decimal fraction he writes 09., and he omits the dot on the left. The zero plays here the rôle of decimal separatrix.

¹ I have used the edition of 1612 which bears the following title: *Bartholamei | Pitisci Grunbergensis | Silesij | Trigonometriae | Sive. De dimensione Triangulor[um] Libri Quinque. Item | Problematum variorum. [m] nempe | Geodaeticorum, | Altimetricorum, | Geographicorum, | Gnomonicorum, et | Astronomicorum: | Libri Decem. | Editio Tertia. | Cui recens accessit Pro | blematum Architectonicorum Liber | unus | Francofurti. | Typis Nicolai Hofmanni: | Sumptibus Ioniae Rosae. | M.DCXII.*

² Quoted from J. Tropske, *op. cit.*, Vol. I (1921), p. 140.

The dots appearing here are simply the punctuation marks written after (sometimes also before) a number which appears in the running text of most medieval manuscripts and many early printed books on mathematics. For example, Clavius¹ wrote in 1606: "Deinde quia minor est $\frac{4}{7}$. quam $\frac{3}{8}$. erit per propos .8. minutarium libri 9. Euclid. minor proportio 4. ad 7. quam 3. ad 5."

Pitiscus makes extensive use of decimal fractions. In the first five books of his *Trigonometria* the decimal fractions are not preceded by integral values. The fractional numerals are preceded by a zero; thus on page 44 he writes 02679492 (our 0.2679492) and finds its square root which he writes 05176381 (our 0.5176381). Given an arc and its chord, he finds (p. 54) the chord of one-third that arc. This leads to the equation (in modern symbols) $3x - x^3 = .5176381$, the radius being unity. In the solution of this equation by approximation he obtains successively 01, 017, 0174 . . . and finally 01743114. In computing, he squares and cubes each of these numbers. Of 017, the square is given as 00289, the cube as 0004913. This proves that Pitiscus understood operations with decimals. In squaring 017 appears the following:

$$\begin{array}{r} 001.7 \\ 27 \\ 189 \\ \hline 002\ 89.4 \end{array}$$

What rôle do these dots play? If we put $a = .1$, $b = .7$, then $(a+b)^2 = a^2 + (2a+b)b$; $001 = a^2$, $027 = (2a+b)b$, $00189 = (2a+b)b$, $00289 = (a+b)^2$. The dot in 001.7 serves simply as a separator between the 001 and the digit 7, found in the second step of the approximation. Similarly, in 00289.4, the dot separates 00289 and the digit 4, found in the third step of the approximation. It is clear that the dots used by Pitiscus in the foregoing approximation are not decimal points.

The part of Pitiscus' *Trigonometria* (1612) which bears the title "Problematum variarum . . . libri vndecim" begins a new pagination. Decimal fractions are used extensively, but integral parts appear and a vertical bar is used as decimal separatrix, as (p. 12) where he says, "pro . . . 13|00024. assumo 13. fractione scilicet $\frac{24}{100000}$ neglecta." ("For 13.00024 I assume 13, the fraction, namely, $\frac{24}{100000}$ being neglected.") Here again he displays his understanding of decimals, and he uses the dot for other purposes than a decimal separatrix. The writer has carefully examined every appearance of

¹ Christophori Clavius . . . *Geometria practica* (Mogvntiae, 1606), p. 343.

dots in the processes of arithmetical calculation, but has failed to find the dot used as a decimal separatrix. There are in the Pitiscus of 1612 three notations for decimal fractions, the three exhibited in 0522 (our .522), 5|269 (our 5.269), and the form (p. 9) of common fractions, $121\frac{4}{10}\frac{3}{10}$. In one case (p. 11) there occurs the tautological notation $29|_{10}\frac{9}{10}$ (our 29.95).

280. But it has been affirmed that Pitiscus used the decimal point in his trigonometric Table. Indeed, the dot does appear in the Table of 1612 hundreds of times. Is it used as a decimal point? Let us quote from Pitiscus (p. 34): "Therefore the radius for the making of these Tables is to be taken so much the more, that there may be no error in so many of the figures towards the left hand, as you will have placed in the Tables: And as for the superfluous numbers they are to be cut off from the right hand toward the left, after the ending of the calculation. So did Regiomontanus, when he would calculate the tables of sines to the radius of 6000000; he took the radius 60000000000. and after the computation was ended, he cut off from every sine so found, from the right hand toward the left four figures, so Rhaeticus when he would calculate a table of sines to the radius of 100000000000 took for the radius 1000000000000000 and after the calculation was done, he cut off from every sine found from the right hand toward the left five figures: But I, to find out the numbers in the beginning of the Table, took the radius of 100000 00000 00000 00000 00000. But in the Canon itself have taken the radius divers numbers for necessity sake: As hereafter in his place shall be declared."

On page 83 Pitiscus states that the radius assumed is unity followed by 5, 7, 8, 9, 10, 11, or 12 ciphers, according to need. In solving problems he takes, on page 134, the radius 10^7 and writes $\sin 61^\circ 46' = 8810284$ (the number in the table is 88102.838); on page 7 ("Probl. var.") he takes the radius 10^5 and writes $\sin 41^\circ 10' = 65825$ (the number in the Table is 66825.16). Many examples are worked, but in no operation are the trigonometric values taken from the Table written down as decimal fractions. In further illustration we copy the following numerical values from the Table of 1612 (which contains sines, tangents, and secants):

" $\sin 2'' = 97$	$\sec 3'' = 100000.00001.06$
$\sin 3'' = 1.45$	$\sec 2^\circ 30' = 100095.2685.$
$\tan 3'' = 1.45$	$\sec 3^\circ 30' = 100186.869$
$\sin 89^\circ 59' 59'' = 99999.99999.88$	
$\tan 89^\circ 59' 59'' = 20626480624.$	
$\sin 30^\circ 31' = 50778.90$	$\sec 30^\circ 31' = 116079.10''$

To explain all these numbers the radius must be taken 10^{12} . The 100000.00001.06 is an integer. The dot on the right is placed between tens and hundreds. The dot on the left is placed between millions and tens of millions.

When a number in the Table contains two dots, the left one is always between millions and tens of millions. The right-hand dot is between tens and hundreds, except in the case of the secants of angles between $0^{\circ}19'$ and $2^{\circ}31'$ and in the case of sines of angles between $87^{\circ}59'$ and $89^{\circ}40'$; in these cases the right-hand dot is placed (probably through a printer's error) between hundreds and thousands (see sec. $2^{\circ}30'$). The tangent of $89^{\circ}59'59''$ (given above) is really 20626480624-0000000, when the radius is 10^{12} . All the figures below ten millions are omitted from the Table in this and similar cases of large functional values.

If a sine or tangent has one dot in the Table and the secant for the same angle has two dots, then the one dot for the sine or tangent lies between millions and tens of millions (see $\sin 3''$, sec $3''$).

If both the sine and secant of an angle have only one dot in the Table and $r = 10^{12}$, that dot lies between millions and tens of millions (see $\sin 30^{\circ}31'$ and sec $30^{\circ}31'$). If the sine or tangent of an angle has no dots whatever (like $\sin 2''$), then the figures are located immediately below the place for tens of millions. For all angles above $2^{\circ}30'$ and below 88° the numbers in the Table contain each one and only one dot. If that dot were looked upon as a decimal point, correct results could be secured by the use of that part of the Table. It would imply that the radius is always to be taken 10^5 . But this interpretation is invalid for any one of the following reasons: (1) Pitiscus does not always take the $r = 10^5$ (in his early examples he takes $r = 10^7$), and he explicitly says that the radius may be taken 10^5 , 10^7 , 10^8 , 10^9 , 10^{10} , 10^{11} , or 10^{12} , to suit the degrees of accuracy demanded in the solution. (2) In the numerous illustrative solutions of problems the numbers taken from the Table are always in integral form. (3) The two dots appearing in some numbers in the Table could not both be decimal points. (4) The numbers in the Table containing no dots could not be integers.

The dots were inserted to facilitate the selection of the trigonometric values for any given radius. For $r = 10^5$, only the figures lying to the left of the dot between millions and tens of millions were copied. For $r = 10^{10}$, the figures to the left of the dot between tens and hundreds were chosen, zeroes being supplied in cases like $\sin 30^{\circ}31'$, where there was only one dot, so as to yield $\sin 30^{\circ}31' = 5077890000$.

For $r=10^7$, the figures for 10^6 and the two following figures were copied from the Table, yielding, for example, $\sin 30^\circ 31' = 5077890$. Similarly for other cases.

In a Table¹ which Pitiscus brought out in 1613 one finds the sine of $2^\circ 52' 30''$ given as 5015.71617.47294, thus indicating a different place assignment of the dots from that of 1612. In our modern tables the natural sine of $2^\circ 52' 30''$ is given as .05015. This is in harmony with the statement of Pitiscus on the title-page that the Tables are computed "ad radium 1.00000.00000.00000." The observation to be stressed is that these numbers in the Table of Pitiscus (1613) are not decimal fractions, but integers.

Our conclusions, therefore, are that Pitiscus made extended use of decimal fractions, but that the honor of introducing the dot as the separatrix between units and tenths must be assigned to others.

J. Ginsburg has made a discovery of the occurrence of the dot in the position of a decimal separatrix, which he courteously permits to be noted here previous to the publication of his own account of it. He has found the dot in Clavius' *Astrolabe*, published in Rome in 1593, where it occurs in a table of sines and in the explanation of that table (p. 228). The table gives $\sin 16^\circ 12' = 2789911$ and $\sin 16^\circ 13' = 2792704$. Clavius places in a separate column 46.5 as a correction to be made for every second of arc between $16^\circ 12'$ and $16^\circ 13'$. He obtained this 46.5 by finding the difference 2793 "between the two sines 2789911.2792704," and dividing that difference by 60. He identifies 46.5 as signifying $46\frac{1}{2}$. This dot separates units and tenths. In his works, Clavius uses the dot regularly to separate any two successive numbers. The very sentence which contains 46.5 contains also the integers "2789911.2792704." The question arises, did Clavius in that sentence use both dots as general separators of two pairs of numbers, of which one pair happened to be the integers 46 and the five-tenths, or did Clavius consciously use the dot in 46.5 in a more restricted sense as a decimal separatrix? His use of the plural "duo hi numeri 46.5" goes rather against the latter interpretation. If a more general and more complete statement can be found in Clavius, these doubts may be removed. In his *Algebra* of 1608, Clavius writes all decimal fractions in the form of common fractions. Nevertheless, Clavius unquestionably deserves a place in the history of the introduction of the dot as a decimal separatrix.

More explicit in statement was John Napier who, in his *Rabdologia*

¹ B. Pitiscus, *Thesaurus mathematicus, sive Canon sinum* (Francofurti, 1613), p. 19.

of 1617, recommended the use of a "period or comma" and uses the comma in his division. Napier's *Constructio* (first printed in 1619) was written before 1617 (the year of his death). In section 5 he says: "Whatever is written after the period is a fraction," and he actually uses the period. In the Leyden edition of the *Constructio* (1620) one finds (p. 6) "25.803. idem quod $25\frac{8}{10}\frac{0}{10}\frac{3}{10}$."

281. The point occurs in E. Wright's 1616 edition of Napier's *Descriptio*, but no evidence has been advanced, thus far, to show that the sign was intended as a separator of units and tenths, and not as a more general separator as in Pitiscus.

282. *The decimal comma and point of Napier.*—That John Napier in his *Rabdologia* of 1617 introduced the comma and point as separators of units and tenths, and demonstrated that the comma was intended to be used in this manner by performing a division, and properly placing the comma in the quotient, is admitted by all historians. But there are still historians inclined to the belief that he was not the first to use the point or comma as a separatrix between units and tenths. We copy from Napier the following: "Since there is the same facility in working with these fractions as with whole numbers, you will be able after completing the ordinary division, and adding a period or comma, as in the margin, to add to the dividend or to the remainder one cypher to obtain

$$\begin{array}{r}
 64 \\
 136 \\
 316 \\
 118,000 \\
 141 \\
 402 \\
 429 \\
 861094,000(1993,273 \\
 432 \\
 3888 \\
 3888 \\
 1296 \\
 \hline

 3024 \\
 .1296
 \end{array}$$

tenths, two for hundredths, three for thousandths, or more afterwards as required: And with these you will be able to proceed with the working as above. For instance, in the preceding example, here repeated, to which we have added three cyphers, the quotient will

become 1 9 9 3, 2 7 3, which signifies 1 9 9 3 units and 2 7 3 thousandth parts or $1\frac{273}{1000}$.¹

Napier gives in the *Rabdologia* only three examples in which decimals occur, and even here he uses in the text the sexagesimal exponents for the decimals in the statement of the results.² Thus he writes 1994.9160 as 1994,9 1 6 0 ; in the edition brought out at Leyden in 1626, the circles used by S. Stevin in his notation of decimals are used in place of Napier's sexagesimal exponents.

Before 1617, Napier used the decimal point in his *Constructio*, where he explains the notation in sections 4, 5, and 47, but the *Constructio* was not published until 1619, as already stated above. In section 5 he says: "Whatever is written after the period is a fraction," and he actually uses the period. But in the passage we quoted from *Rabdologia* he speaks of a "period or comma" and actually uses a comma in his illustration. Thus, Napier vacillated between the period and the comma; mathematicians have been vacillating in this matter ever since.

In the 1620 edition³ of the *Constructio*, brought out in Leyden, one reads: "Vt 10000000.04, valet idem, quod $10000000\frac{4}{100}$. Item 25.803. idem quod $25\frac{803}{1000}$. Item 9999998.0005021, idem valet quod $9999998\frac{5021}{1000000}$. & sic de caeteris."

283. *Seventeenth-century notations after 1617*.—The dot or comma attained no ascendancy over other notations during the seventeenth century.

In 1623 John Johnson (the *survaighour*)⁴ published an *Arithmetick* which stresses decimal fractions and modifies the notation of Stevin by omitting the circles. Thus, £ 3. 2 2 9 1 6 is written

$$£ 3 \left| \begin{smallmatrix} 1. & 2. & 3. & 4. & 5. \\ 2 & 2 & 9 & 1 & 6 \end{smallmatrix} \right.,$$

while later in the text there occurs the symbolism 31 | 2500 and 54 | 2625, and also the more cautious "358 | 49411 fifths" for our 358.49411.

¹ John Napier, *Rabdologia* (Edinburgh, 1617), Book I, chap. iv. This passage is copied by W. R. Macdonald, in his translation of John Napier's *Constructio* (Edinburgh, 1889), p. 89.

⁴ From A. de Morgan in *Companion to the British Almanac* (1851), p. 12.

Henry Briggs¹ drew a horizontal line under the numerals in the decimal part which appeared in smaller type and in an elevated position; Briggs wrote 5^{9321} for our 5.9321. But in his Tables of 1624 he employs commas, not exclusively as a decimal separatrix, although one of the commas used for separation falls in the right place between units and tenths. He gives $-0,22724,3780$ as the logarithm of $\frac{1}{2}^{\frac{2}{7}}$.

A. Girard² in his *Invention nouvelle* of 1629 uses the comma on one occasion; he finds one root of a cubic equation to be $1_1^{\frac{5}{10}\frac{3}{10}\frac{2}{10}}$ and then explains that the three roots expressed in decimals are 1,532 and 347 and $-1,879$. The 347 is .347; did Girard consider the comma unnecessary when there was no integral part?

Bürgi's and Kepler's notation is found again in a work which appeared in Poland from the pen of Joach. Stegman,³ he writes 39(063. It occurs again in a geometry written by the Swiss Joh. Ardüser.⁴

William Oughtred adopted the sign $2\overline{5}$ in his *Clavis mathematicae* of 1631 and in his later publications.

In the second edition of Wingate's *Arithmetic* (1650; ed. John Kersey) the decimal point is used, thus: .25, .0025.

In 1651 Robert Jager⁵ says that the common way of natural arithmetic being tedious and prolix, God in his mercy directed him to what he published; he writes upon decimals, in which $16|\overline{7249}$ is our 16.7249.

Richard Balam⁶ used the colon and wrote 3:04 for our 3.04. This same symbolism was employed by Richard Rawlyns,⁷ of Great Yarmouth, in England, and by H. Meissner⁸ in Germany.

Sometimes one encounters a superposition of one notation upon another, as if one notation alone might not be understood. Thus F. van Schooten¹ writes 58,5 ① for 58.5, and 638,82 ② for 638.82. Tobias Beutel² writes $645.\overset{8}{1}\overset{7}{0}\overset{9}{0}$. A. Tacquet³ sometimes writes $25.8\overset{i}{0}\overset{ii}{0}\overset{iii}{0}\overset{iv}{7}\overset{v}{9}$, at other times omits the dot, or the Roman superscripts.

Samuel Foster⁴ of Gresham College, London, writes $31.\overset{008}{\rule{1.5cm}{0.4pt}}$; he does not rely upon the dot alone, but adds the horizontal line found in Briggs.

Johann Caramuel⁵ of Lobkowitz in Bohemia used two horizontal parallel lines, like our sign of equality, as $22=3$ for 22.3, also $92=$
 $123,345$ for 92.123345 . In a Parisian text by Jean Prestet⁶ 272097792 is given for 272.097792 ; this mode of writing had been sometimes used by Stevin about a century before Prestet, and in 1603 by Beyer.

William Molyneux⁷ of Dublin had three notations; he frequently used the comma bent toward the right, as in 30,24. N. Mercator⁸ in his *Logarithmotechnia* and Dechales⁹ in his course of mathematics used the notation as in 12[345].

284. The great variety of forms for separatrix is commented on by Samuel Jeake in 1696 as follows: "For distinguishing of the Decimal Fraction from Integers, it may truly be said, *Quot Homines, tot Sententiae*; every one fancying severally. For some call the Tenth Parts, the *Primes*; the Hundredth Parts, *Seconds*; the Thousandth Parts, *Thirds*, etc. and mark them with *Indices* equivalent over their heads. As to express 34 integers and $1\overset{1}{0}\overset{4}{0}\overset{2}{0}\overset{6}{0}$ Parts of an Unit, they do it thus, $\overset{1}{1} \overset{1}{1} \overset{1}{1} \overset{1}{1} \overset{1}{1} \overset{(1)}{1} \overset{(2)}{2} \overset{(3)}{3} \overset{(4)}{4}$ 34.1. 4. 2. 6. Or thus, 34.1. 4. 2. 6. Others thus, $34,1426''''$; or thus, $34,1426^{(4)}$. And some thus, 34.1 . 4 . 2 . 6 . setting the Decimal Parts

at little more than ordinary distance one from the other. . . . Others distinguish the Integers from the Decimal Parts only by placing a Cöma before the Decimal Parts thus, 34,1426; a good way, and very useful. Others draw a Line under the Decimals thus, 34¹⁴²⁶, writing them in smaller Figures than the Integers. And others, though they use the Cöma in the work for the best way of distinguishing them, yet after the work is done, they use a Rectangular Line after the place of the Units, called *Separatrix*, a separating Line, because it separates the Decimal Parts from the Integers, thus 34|1426. And sometimes the Cöma is inverted thus, 34'1426, contrary to the true Cöma, and set at top. I sometimes use the one, and sometimes the other, as cometh to hand." The author generally uses the comma. This detailed statement from this seventeenth-century writer is remarkable for the omission of the point as a decimal separatrix.

285. *Eighteenth-century discard of clumsy notations.*—The chaos in notations for decimal fractions gradually gave way to a semblance of order. The situation reduced itself to trials of strength between the comma and the dot as separatrices. To be sure, one finds that over a century after the introduction of the decimal point there were authors who used besides the dot or comma the strokes or Roman numerals to indicate primes, seconds, thirds, etc. Thus, Chelucci¹ in 1738 writes

$$\begin{array}{cccccccc} 0 & I & II & III & IV & & I & IV & & II & V \\ 5.8 & 6 & 4 & 2 & & 5 & \text{for } 4.2005, & 3.5 & 7 & \text{for } 3.05007. \end{array}$$

W. Whiston² of Cambridge used the semicolon a few times, as in 0;9985, though ordinarily he preferred the comma. O. Gherli³ in Modena, Italy, states that some use the sign 35|345, but he himself uses the point. E. Wells⁴ in 1713 begins with 75.25, but later in his arithmetic introduces Oughtred's $\overline{75}$. Joseph Raphson's translation into English of I. Newton's *Universal Arithmetick* (1728),⁵ contains 732, $\overline{569}$ for our 732.569. L'Abbé Deidier⁶ of Paris writes the

⁵ *Universal Arithmetick, or Treatise of Arithmetical Composition and Resolution . . .* transl. by the late Mr. Joseph Raphson, & revised and corrected by Mr. Cunn (2d ed.; London, 1728), p. 2.

⁶ L'Abbé Deidier, *L'Arithmétique des Géomètres, ou nouveaux élémens de mathématiques* (Paris, 1739), p. 413.

decimal point and also the strokes for tenths, hundredths, etc. He says: "Pour ajouter ensemble $32.6' 3'' 4'''$ et $8.5' 4'' .3'''$ —

$$\begin{array}{r} 32\ 6\ 3\ 4^{\text{III}} \\ 8\ 5\ 4\ 3^{\text{III}} \\ \hline 41\ 1\ 7\ 7^{\text{III}} \end{array}$$

A somewhat unusual procedure is found in Sherwin's *Tables*¹ of 1741, where a number placed inside a parenthesis is used to designate the number of zeroes that precede the first significant figure in a decimal; thus, (4) 2677 means .00002677.

In the eighteenth century, trials of strength between the comma and the dot as the separatrix were complicated by the fact that Leibniz had proposed the dot as the symbol of multiplication, a proposal which was championed by the German textbook writer Christian Wolf and which met with favorable reception throughout the Continent. And yet Wolf² himself in 1713 used the dot also as separatrix, as "loco $5, \frac{4}{10} \frac{7}{10} \frac{0}{10} \frac{0}{10}$ scribimus 5.0047." As a symbol for multiplication the dot was seldom used in England during the eighteenth century, Oughtred's \times being generally preferred. For this reason, the dot as a separatrix enjoyed an advantage in England during the eighteenth century which it did not enjoy on the Continent. Of fifteen British books of that period, which we chose at random, nine used the dot and six the comma. In the nineteenth century hardly any British authors employed the comma as separatrix.

In Germany, France, and Spain the comma, during the eighteenth century, had the lead over the dot, as a separatrix. During that century the most determined continental stand in favor of the dot was made in Belgium³ and Italy.⁴ But in recent years the comma has finally won out in both countries.

¹ H. Sherwin, *Mathematical Tables* (3d ed.; rev. William Gardiner, London, 1741), p. 48.

² Christian Wolf, *Elementa matheseos universae*, Tomus I (Halle, 1713), p. 77.

³ Désiré André, *Des Notations Mathématiques* (Paris, 1909), p. 19, 20.

⁴ Among eighteenth-century writers in Italy using the dot are Paulino A. S. Josepho Lucensi who in his *Institutiones analyticae* (Rome, 1738) uses it in connection with an older symbolism, "3.05007"; G. M. della Torre, *Istituzioni arismetice* (Padua, 1768); Odoardo Gherli, *Elementi delle matematiche pure*, Modena, Tomo I (1770); Peter Ferroni, *Magnitudinum exponentialium logarithmorum et trigonometriae sublimis theoria* (Florence, 1782); F. A. Tortorella, *Arithmetica degl'idioti* (Naples, 1794).

286. *Nineteenth century: different positions for dot and comma.*—

In the nineteenth century the dot became, in England, the favorite separatrix symbol. When the brilliant but erratic Randolph Churchill critically spoke of the “damned little dots,” he paid scant respect to what was dear to British mathematicians. In that century the dot came to serve in England in a double capacity, as the decimal symbol and as a symbol for multiplication.

Nor did these two dots introduce confusion, because (if we may use a situation suggested by Shakespeare) the symbols were placed in Romeo and Juliet positions, the Juliet dot stood on high, above Romeo’s reach, her joy reduced to a decimal over his departure, while Romeo below had his griefs multiplied and was “a thousand times the worse” for want of her light. Thus, $2\cdot5$ means $2\frac{5}{10}$, while 2.5 equals 10. It is difficult to bring about a general agreement of this kind, but it was achieved in Great Britain in the course of a little over half a century. Charles Hutton¹ said in 1795: “I place the point near the upper part of the figures, as was done also by Newton, a method which prevents the separatrix from being confounded with mere marks of punctuation.” In the Latin edition² of Newton’s *Arithmetica universalis* (1707) one finds, “Sic numerus 732’|569. denotat septingentas triginta duas unitates, . . . qui et sic 732,|569, vel sic 732·569. vel etiam sic 732̄569, nunnunquam scribitur . . . 57104’2083 . . . 0’064.” The use of the comma prevails; it is usually placed high, but not always. In Horsely’s and Castillon’s editions of Newton’s *Arithmetica universalis* (1799) one finds in a few places the decimal notation 35’72; it is here not the point but the comma that is placed on high. Probably as early as the time of Hutton the expression “decimal point” had come to be the synonym for “separatrix” and was used even when the symbol was not a point. In most places in Horsely’s and Castillon’s editions of Newton’s works, the comma 2,5 is used, and only in rare instances the point 2.5. The sign $2\cdot5$ was used in England by H. Clarke³ as early as 1777, and by William Dickson⁴ in 1800. After the time of Hutton the $2\cdot5$ symbolism was adopted by Peter Barlow (1814) and James Mitchell (1823) in their mathematical dictionaries. Augustus de Morgan states in his *Arithmetic*: “The

³ H. Clarke, *Rationale of Circulating Numbers* (London, 1777).

⁴ W. Dickson in *Philosophical Transactions*, Vol. VIII (London, 1800), p. 231.

student is recommended always to write the decimal point in a line with the top of the figures, or in the middle, as is done here, and never at the bottom. The reason is that it is usual in the higher branches of mathematics to use a point placed between two numbers or letters which are multiplied together."¹ A similar statement is made in 1852 by T. P. Kirkman.² Finally, the use of this notation in Todhunter's texts secured its general adoption in Great Britain.

The extension of the usefulness of the comma or point by assigning it different vertical positions was made in the arithmetic of Sir Jonas Moore³ who used an elevated and inverted comma, 116'64. This notation never became popular, yet has maintained itself to the present time. Daniel Adams,⁴ in New Hampshire, used it, also Juan de Dios Salazar⁵ in Peru, Don Gabriel Ciscar⁶ of Mexico, A. de la Rosa Toro⁷ of Lima in Peru, and Federico Villareal⁸ of Lima. The elevated and inverted comma occurs in many, but not all, the articles using decimal fractions in the *Enciclopedia-universal ilustrada Europeo-Americana* (Barcelona, 1924).

Somewhat wider distribution was enjoyed by the elevated but not inverted comma, as in 2'5. Attention has already been called to the occurrence of this symbolism, a few times, in Horsley's edition of Newton's *Arithmetica universalis*. It appeared also in W. Whiston's edition of the same work in 1707 (p. 15). Juan de Dios Salazar of Peru, who used the elevated inverted comma, also uses this. It is Spain and the Spanish-American countries which lead in the use of this notation. De La-Rosa Toro, who used the inverted comma, also used this. The 2'5 is found in Luis Monsante⁹ of Lima; in Maximo

Vazquez¹ of Lima; in Manuel Torres Torija² of Mexico; in D. J. Cortazár³ of Madrid. And yet, the Spanish-speaking countries did not enjoy the monopoly of this symbolism. One finds the decimal comma placed in an elevated position, 2⁵, by Louis Bertrand⁴ of Geneva, Switzerland.

Other writers use an inverted wedge-shaped comma,⁵ in a lower position, thus: 2_▲5. In Scandinavia and Denmark the dot and the comma have had a very close race, the comma being now in the lead. The practice is also widely prevalent, in those countries, of printing the decimal part of a number in smaller type than the integral part.⁶ Thus one frequently finds there the notations 2_{,5} and 2.₅. To sum up, in books printed within thirty-five years we have found the decimal notations⁷ 2·5, 2⁵, 2₅, 2⁵, 2_▲5, 2_{,5}, 2.₅.

287. The earliest arithmetic printed on the American continent which described decimal fractions came from the pen of Greenwood,⁸ professor at Harvard College. He gives as the mark of separation "a Comma, a Period, or the like," but actually uses a comma. The arithmetic of "George Fisher" (Mrs. Slack), brought out in England, and also her *The American Instructor* (Philadelphia, 1748) contain both the comma and the period. Dilworth's *The Schoolmaster's Assistant*, an English book republished in America (Philadelphia, 1733), used the period. In the United States the decimal point⁹ has always had the

⁵ As in A. F. Vallin, *Aritmética para los niños* (41st ed.; Madrid, 1889), p. 66.

⁶ Gustaf Haglund, *Samtying of Öfningsexempel till Lärabok i Algebra*, Fjerde Upplagan (Stockholm, 1884), p. 19; *Öfversigt af Kongl. Vetenskaps-Akademiens Förhandlingar*, Vol. LIX (1902; Stockholm, 1902, 1903), p. 183, 329; *Oversigt over det Kongelige Danske Videnskabernes Selskabs, Fordhandlingar* (1915; Kobenhavn, 1915), p. 33, 35, 481, 493, 545.

⁷ An unusual use of the elevated comma is found in F. G. Gausz's *Fünfstellige vollständige Logar. u. Trig. Tafeln* (Halle a. S., 1906), p. 125; a table of squares of numbers proceeds from $N=0'00$ to $N=10'00$. If the square of 63 is wanted, take the form 6'3; its square is 39'6900. Hence $63^2=3969$.

⁸ Isaac Greenwood, *Arithmetick Vulgar and Decimal* (Boston, 1729), p. 49. See facsimile of a page showing decimal notation in L. C. Karpinski, *History of Arithmetic* (Chicago, New York, 1925), p. 134.

⁹ Of interest is Chauncey Lee's explanation in his *American Accomptant* (Lasingburgh, 1797), p. 54, that, in writing denominate numbers, he separates

lead over the comma, but during the latter part of the eighteenth and the first half of the nineteenth century the comma in the position of 2,5 was used quite extensively. During 1825–50 it was the influence of French texts which favored the comma. We have seen that Daniel Adams used 2'5 in 1827, but in 1807 he¹ had employed the ordinary 25,17 and ,375. Since about 1850 the dot has been used almost exclusively. Several times the English elevated dot was used in books printed in the United States. The notation 2·5 is found in Thomas Sarjeant's *Arithmetic*,² in F. Nichols' *Trigonometry*,³ in American editions of Hutton's *Course of Mathematics* that appeared in the interval 1812–31, in Samuel Webber's *Mathematics*,⁴ in William Griev's *Mechanics Calculator*, from the fifth Glasgow edition (Philadelphia, 1842), in *The Mathematical Diary* of R. Adrain⁵ about 1825, in Thomas Sherwin's *Common School Algebra* (Boston, 1867; 1st ed., 1845), in George R. Perkins' *Practical Arithmetic* (New York, 1852). Sherwin writes: "To distinguish the sign of Multiplication from the period used as a decimal point, the latter is elevated by inverting the type, while the former is larger and placed down even with the lower extremities of the figures or letters between which it stands." In 1881 George Bruce Halsted⁶ placed the decimal point halfway up and the multiplication point low.

It is difficult to assign definitely the reason why the notation 2·5 failed of general adoption in the United States. Perhaps it was due to mere chance. Men of influence, such as Benjamin Peirce, Elias Loomis, Charles Davies, and Edward Olney, did not happen to become interested in this detail. America had no one of the influence of De Morgan and Todhunter in England, to force the issue in favor of 2·5. As a result, 2·5 had for a while in America a double meaning, namely, 2 5/10 and 2 times 5. As long as the dot was seldom used to

the denominations "in a vulgar table" by two commas, but "in a decimal table" by the decimal point; he writes £ 175,, 15,, 9, and 1.41.

⁶ George Bruce Halsted, *Elementary Treatise on Mensuration* (Boston, 1881).

express multiplication, no great inconvenience resulted, but about 1880 the need of a distinction arose. The decimal notation was at that time thoroughly established in this country, as 2.5, and the dot for multiplication was elevated to a central position. Thus with us $2 \cdot 5$ means 2 times 5.

Comparing our present practice with the British the situation is this: We write the decimal point low, they write it high; we place the multiplication dot halfway up, they place it low. Occasionally one finds the dot placed high to mark multiplication also in German books, as, for example, in Friedrich Meyer¹ who writes $2 \cdot 3 = 6$.

288. It is a notable circumstance that at the present time the modern British decimal notation is also the notation in use in Austria where one finds the decimal point placed high, but the custom does not seem to prevail through any influence emanating from England. In the eighteenth century P. Mako² everywhere used the comma, as in 3,784. F. S. Mozhnik³ in 1839 uses the comma for decimal fractions, as in 3,1344, and writes the product " $2 \cdot 3 \cdot n$." The *Sitzungsberichte der philosophisch-historischen Classe d. K. Akademie der Wissenschaften*, Erster Band (Wien, 1848), contains decimal fractions in many articles and tables, but always with the low dot or low comma as decimal separatrix; the low dot is used also for multiplication, as in " $1.2.3 \cdot \cdot r$."

But the latter part of the nineteenth century brought a change. The decimal point is placed high, as in $1 \cdot 63$, by I. Lemoch⁴ of Lemberg. N. Fialkowski of Vienna in 1863 uses the elevated dot⁵ and also in 1892.⁶ The same practice is followed by A. Steinhauser of Vienna,⁷ by Johann Spielmann⁸ and Richard Supplantschitsch,⁹ and by Karl

¹ Friedrich Meyer, *Dritter Cursus der Planimetrie* (Halle a/S., 1885), p. 5.

⁹ Richard Supplantschitsch, *Mathematisches Unterrichtswerk, Lehrbuch der Geometrie* (Wien, 1910), p. 91.

Rosenberg.¹ Karl Zahradníček² writes $0\cdot35679.1\cdot0765.1\cdot9223.0\cdot3358$, where the lower dots signify multiplication and the upper dots are decimal points. In the same way K. Wolletz³ writes $(-0\cdot0462).0\cdot0056$.

An isolated instance of the use of the elevated dot as decimal separatrix in Italy is found in G. Peano.⁴

In France the comma placed low is the ordinary decimal separatrix in mathematical texts. But the dot and also the comma are used in marking off digits of large numbers into periods. Thus, in a political and literary journal of Paris (1908)⁵ one finds "2,251,000 drachmes," "Fr. 2.638.370 75," the francs and centimes being separated by a vacant place. One finds also "601,659 francs 05" for Fr. 601659. 05. It does not seem customary to separate the francs from centimes by a comma or dot.

That no general agreement in the notation for decimal fractions exists at the present time is evident from the publication of the International Mathematical Congress in Strasbourg (1920), where decimals are expressed by commas⁶ as in 2,5 and also by dots⁷ as in 2.5. In that volume a dot, placed at the lower border of a line, is used also to indicate multiplication.⁸

The opinion of an American committee of mathematicians is expressed in the following: "Owing to the frequent use of the letter x , it is preferable to use the dot (a raised period) for multiplication in the few cases in which any symbol is necessary. For example, in a case like $1\cdot2\cdot3\ldots(x-1)\cdot x$, the center dot is preferable to the symbol \times ; but in cases like $2a(x-a)$ no symbol is necessary. The committee recognizes that the period (as in $a.b$) is more nearly international than the center dot (as in $a\cdot b$); but inasmuch as the period will continue to be used in this country as a decimal point,

⁸ *Op. cit.*, p. 153, 252, 545.

it is likely to cause confusion, to elementary pupils at least, to attempt to use it as a symbol for multiplication."¹

289. *Signs for repeating decimals.*—In the case of repeating decimals, perhaps the earliest writer to use a special notation for their designation was John Marsh,² who, "to avoid the Trouble for the future of writing down the Given Repetend or Circulate, whether Single or Compound, more than once," distinguishes each "by placing a Period over the first Figure, or over the first and last Figures of the given Repetend." Likewise, John Robertson³ wrote $0,\dot{3}$ for 0,33 . . . , $0,\dot{2}\dot{3}$ for 0,2323 . . . , $0,\dot{7}\dot{8}\dot{5}$ for 0,785785. . . . H. Clarke⁴ adopted the signs $\dot{.6}$ for .666 . . . , $\dot{.64}\dot{2}$ for .642642. . . . A choice favoring the dot is shown by Nicolas Pike⁵ who writes, $\dot{3}7\dot{9}$, and by Robert Pott⁶ and James Pryde⁷ who write $\dot{3}$, $\dot{4}\dot{5}$, $\dot{34}\dot{5}\dot{6}\dot{7}$. A return to accents is seen in the *Dictionary* of Davies and Peck⁸ who place accents over the first, or over the first and last figure, of the repetend, thus: $\cdot'2$, $\cdot'5723'$, $2.4'18'$.

SIGNS OF POWERS

290. *General remarks.*—An ancient symbol for squaring a number occurs in a hieratic Egyptian papyrus of the late Middle Empire, now in the Museum of Fine Arts in Moscow.⁹ In the part containing the computation of the volume of a frustrated pyramid of square base there occurs a hieratic term, containing a pair of walking legs Λ and signifying "make in going," that is, squaring the number. The Diophantine notation for powers is explained in § 101, the Hindu notation in §§ 106, 110, 112, the Arabic in § 116, that of Michael Psellus in § 117. The additive principle in marking powers is referred

to in §§ 101, 111, 112, 124. The multiplicative principle in marking powers is elucidated in §§ 101, 111, 116, 135, 142.

Before proceeding further, it seems desirable to direct attention to certain Arabic words used in algebra and their translations into Latin. There arose a curious discrepancy in the choice of the principal unknown quantity; should it be what we call x , or should it be x^2 ? al-Khowârizmî and the older Arabs looked upon x^2 as the principal unknown, and called it *māl* ("assets," "sum of money").¹ This viewpoint may have come to them from India. Accordingly, x (the Arabic *jidr*, "plant-root," "basis," "lowest part") must be the square root of *māl* and is found from the equation to which the problem gives rise. By squaring x the sum of money could be ascertained.

Al-Khowârizmî also had a general term for the unknown, *shai* ("thing"); it was interpreted broadly and could stand for either *māl* or *jidr* (x^2 or x). Later, John of Seville, Gerard of Cremona, Leonardo of Pisa, translated the Arabic *jidr* into the Latin *radix*, our x ; the Arabic *shai* into *res*. John of Seville says in his arithmetic:² "Quaeritur ergo, quae res cum. X. radicibus suis idem decies accepta radice sua efficiat 39." ("It is asked, therefore, what thing together with 10 of its roots or what is the same, ten times the root obtained from it, yields 39.") This statement yields the equation $x^2 + 10x = 39$. Later *shai* was also translated as *causa*, a word which Leonardo of Pisa used occasionally for the designation of a second unknown quantity. The Latin *res* was translated into the Italian word *cosa*, and from that evolved the German word *coss* and the English adjective "cossic." We have seen that the abbreviations of the words *cosa* and *cubus*, viz., *co.* and *cu.*, came to be used as algebraic symbols. The words *numerus*, *dragma*, *denarius*, which were often used in connection with a given absolute number, experienced contractions sometimes employed as symbols. Plato of Tivoli,³ in his translation from the Hebrew of the *Liber embadorum* of 1145, used a new term, *latus* ("side"), for the first power of the unknown, x , and the name *embadum* ("content") for the second power, x^2 . The term *latus* was found mainly in early Latin writers drawing from Greek sources and was used later by Ramus (§ 322), Vieta (§ 327), and others.

291. *Double significance of "R" and "l."*—There came to exist considerable confusion on the meaning of terms and symbols, not only

¹ J. Ruska, *Sitzungsberichte Heidelberger Akad., Phil.-hist. Klasse* (1917), Vol. II, p. 61 f.; J. Tropfke, *op. cit.*, Vol. II (2d ed., 1921), p. 106.

² Tropfke, *op. cit.*, Vol. II (2d ed., 1921), p. 107.

³ M. Curtze, *Bibliotheca mathematica* (3d ser.), Vol. I (1900), p. 322, n. 1.

because *res* (x) occasionally was used for x^2 , but more particularly because both *radix* and *latus* had two distinct meanings, namely, x and \sqrt{x} . The determination whether x or \sqrt{x} was meant in any particular case depended on certain niceties of designation which the unwary was in danger of overlooking (§ 137).

The letter l (*latus*) was used by Ramus and Vieta for the designation of roots. In some rare instances it also represented the first power of the unknown x . Thus, in Schoner's edition of Ramus' $5l$ meant $5x$, while $l5$ meant $\sqrt{5}$. Schoner marks the successive powers " l ., q ., c ., bq ., f ., qc ., $b.f$., tq ., cc ." and named them *latus*, *quadratus*, *cubus*, *biquadratus*, and so on. Ramus, in his *Scholarvm mathematicorvm libri unus et triginti* (1569), uses the letter l only for square root, not for x or in the designation of powers of x ; but he uses (p. 253) the words *latus*, *quadratus*, *latus cubi* for x , x^2 , x^3 .

This double use of l is explained by another pupil of Ramus, Bernardus Salignacus,² by the statement that if a number precedes the given sign it is the coefficient of the sign which stands for a power of the unknown, but if the number comes immediately after the l the root of that number is to be extracted. Accordingly, $2q$, $3c$, $5l$ stand respectively for $2x^2$, $3x^3$, $5x$; on the other hand, $l5$, $lc8$, $lbq16$ stand respectively for $\sqrt{5}$, $\sqrt[3]{8}$, $\sqrt[4]{16}$. The double use of the capital L is found in G. Gosselin (§§ 174, 175).

B. Pitiscus³ writes our $3x - x^3$ thus, $3l - 1c$, and its square $9q - 6.bq + 1qc$, while Willebrord Snellius⁴ writes our $5x - 5x^3 + x^5$ in the form $5l - 5c + 1\beta$. W. Oughtred⁵ writes $x^5 - 15x^4 + 160x^3 - 1250x^2 + 6480x = 170304782$ in the form $1qc - 15qq + 160c - 1250q + 6480l = 170304782$.

Both l and R . appear as characters designating the first power

⁴ Willebrord Snellius, *Doctrinae triangulorvm cononicae liber qvatvor* (Leyden, 1627), p. 37.

⁵ William Oughtred, *Clavis mathematicae*, under "De aequationum affectarum resolutione in numeris" (1647 and later editions).

in a work of J. J. Heinlin¹ at Tübingen in 1679. He lets N stand for *unitas, numerus absolutus*, \mathcal{U} , l , R . for *latus vel radix*; z , q . for *quadratus, zensus*; ce , c for *cubus*; zz , qq , bq for *biquadratus*. But he utilizes the three signs \mathcal{U} , l , R also for indicating roots. He speaks² of "*Latus cubicum, vel Radix cubica, cujus nota est Lc. R.c. \mathcal{U} . ce.*"

John Wallis³ in 1655 says "*Est autem lateris l , numerus pyramidalis $l^3 + 3l^2 + 2l$* " and in 1685 writes⁴ " *$l - 2laa + a^4 : \div bb$* ," where the l takes the place of the modern x and the colon is a sign of aggregation, indicating that all three terms are divided by b^2 .

292. The use of R . (*Radix*) to signify root and also power is seen in Leonardo of Pisa (§ 122) and in Luca Pacioli (§§ 136, 137). The sign R was allowed to stand for the first power of the unknown x by Peletier in his algebra, by K. Schott⁵ in 1661, who proceeds to let Q . stand for x^2 , C . for x^3 , *Bigq* or *qq*. for x^4 , *Ss*. for x^5 , *Cq*. for x^6 , *SsB*. for x^7 , *Triq*. or *qqq* for x^8 , *Cc*. for x^9 . One finds R in W. Leybourn's publication of J. Billy's⁶ *Algebra*, where powers are designated by the capital letters N , R , Q , QQ , S , QC , $S2$, QQQ ., and where $x^2 = 20 - x$ is written " $1Q = 20 - 1R$."

Years later the use of R . for x and of \mathcal{P} . (an inverted capital letter E , rounded) for x^2 is given by Tobias Beutel⁷ who writes " $21 \mathcal{P}$, gleich 2100, $1 \mathcal{P}$. gleigh 100, $1R$. gleich 10."

293. *Facsimilis of symbols in manuscripts*.—Some of the forms for radical signs and for x , x^2 , x^3 , x^4 , and x^5 , as found in early German manuscripts and in Widman's book, are tabulated by J. Tropfke, and we reproduce his table in Figure 104.

In the Munich manuscript *cosa* is translated *ding*; the symbols in Figure 104, C2a, seem to be modified d 's. The symbols in C3 are signs for *res*. The manuscripts C3b, C6, C7, C9, H6 bear on the evolution of the German symbol for x . Paleographers incline to the view that it is a modification of the Italian *co*, the o being highly disfigured. In B are given the signs for *dragma* or *numerus*.

294. *Two general plans for marking powers.*—In the early development of algebraic symbolism, no signs were used for the powers of given numbers in an equation. As given numbers and coefficients were not represented by letters in equations before the time of Vieta, but were specifically given in numerals, their powers could be computed on the spot and no symbolism for powers of such numbers was needed. It was different with the unknown numbers, the determination of which constituted the purpose of establishing an equation. In consequence,

(Taken from J. Tropske, *op. cit.*, Vol. II [2d ed., 1921], p. 112.)

one finds the occurrence of symbolic representation of the unknown and its powers during a period extending over a thousand years before the introduction of the literal coefficient and its powers.

For the representation of the unknown there existed two general plans. The first plan was to use some abbreviation of a name signifying unknown quantity and to use also abbreviations of the names signifying the square and the cube of the unknown. Often special symbols were used also for the fifth and higher powers whose orders were prime numbers. Other powers of the unknown, such as the fourth, sixth, eighth powers, were represented by combinations of those symbols. A good illustration is a symbolism of Luca Paciola, in which *co.* (*cosa*) represented x , *ce.* (*censo*) x^2 , *cu.* (*cubo*) x^3 , *p.r.* (*primo relato*) x^5 ; combinations of these yielded *ce.ce.* for x^4 , *ce.cu.* for

x^6 , etc. We have seen these symbols also in Tartaglia and Cardan, in the Portuguese Nuñez (§ 166), the Spanish Perez de Moya in 1652, and Antich Rocha¹ in 1564. We may add that outside of Italy Pacioli's symbols enjoyed their greatest popularity in Spain. To be sure, the German Marco Aurel wrote in 1552 a Spanish algebra (§ 165) which contained the symbols of Rudolff, but it was Perez de Moya and Antich Rocha who set the fashion, for the sixteenth century in Spain; the Italian symbols commanded some attention there even late in the eighteenth century, as is evident from the fourteenth unrevised impression of Perez de Moya's text which appeared at Madrid in 1784. The 1784 impression gives the symbols as shown in Figure 105, and also the explanation, first given in 1562, that the printing office does not have these symbols, for which reason the ordinary letters of the alphabet will be used.² Figure 105 is interesting, for it purports to show the handwritten forms used by De Moya. The symbols are not the German, but are probably derived from them. In a later book, the *Tratado de Mathematicas* (Alcala, 1573), De Moya gives on page 432 the German symbols for the powers of the unknown, all except the first power, for which he gives the crude imitation *Ze*. Antich Rocha, in his *Arithmetica*, folio 253, is partial to capital letters and gives the successive powers thus: *N*, *Co*, *Ce*, *Cu*, *Cce*, *R*, *CeCu*, *RR*, *Ccce*, *Ccu*, etc. The same fondness for capitals is shown in his *Mas* for "more" (§ 320).

We digress further to state that the earliest mathematical work published in America, the *Sumario compendioso* of Juan Diez Freyle³

¹ *Arithmetica* por Antich Rocha de Gerona compuesta, y de varios Auctores recopilada (Barcelona, 1564, also 1565).

² Juan Perez de Moya, *Aritmetica practica, y especulativa* (14th ed.; Madrid, 1784), p. 263: "Por los diez caractéres, que en el precedente capítulo se pusieron, uso estos. Por el qual dicen numero *n*. por la cosa, *co*. por el censo, *ce*. por cubo, *cu*. por censo, de censo, *cce*. por el primero relato, *R*. por el censo, y cubo, *ce.cu*. por segundo relato, *RR*. por censo de censo de censo, *cce*. por cubo de cubo, *ccu*. Esta figura *r*. quiere decir raíz quadrada. Esta figura *rr*. denota raíz quadrada de raíz quadrada. Estas *rrr*. denota raíz cúbica. De estos dos caractéres, *p*. *m*. notarás, que la *p*. quiere decir mas, y la *m*. menos, el uno es copulativo, el otro disyuntivo, sirven para sumar, y restar cantidades diferentes, como adelante mejor entenderás. Quando despues de *r*. se pone *u*. denota raíz quadrada universal: y así *rru*. raíz de raíz quadrada universal: y de esta suerte *rrru*. raíz cúbica universal. Esta figura *ig*. quiere decir igual. Esta *q*. denota cantidad, y así *qs*. cantidades: estos caractéres me ha parecido poner, porque no habia otros en la Imprenta; tú podrás usar, quando hagas demandas, de los que se pusieron en el segundo capítulo, porque son mas breves, en lo demás todos son de una condicion."

³ Edition by D. E. Smith (Boston and London, 1921).

(City of Mexico, 1556) gives six pages to algebra. It contains the words *cosa*, *zenso*, or *censo*, but no abbreviations for them. The work does not use the signs $+$ or $-$, nor the \bar{p} and \bar{m} . It is almost purely rhetorical.

The data which we have presented make it evident that in Perez de Moya, Antich Rocha, and P. Nuñez the symbols of Pacioli are used and that the higher powers are indicated by the combinations of symbols of the lower powers. This *general principle* underlies the notations of Diophantus, the Hindus, the Arabs, and most of the Germans and Italians before the seventeenth century. For convenience we shall call this the "Abbreviate Plan."

Cap. II. En el qual se ponen algunos caractères, que sirven por cantidades proporcionales.

En este capítulo se ponen algunos caractères, dando à cada uno el nombre y valor que le conviene. Los quales son inventados por causa de brevedad; y es de saber, que no es de necesidad, que estos, y no otros hayan de ser, porque cada uno puede usar de lo que quisiere, è inventar mucho mas, procediendo con la proporción que le pareciere. Los caractères son estos.

FIG. 105.—The written algebraic symbols for powers, as given in Perez de Moya's *Arithmetica* (Madrid, 1784), p. 260 (1st ed., 1562). The successive symbols are called *cosa es raíz*, *censo*, *cubo*, *censo de censo*, *primero relato*, *censo y cubo*, *segundo relato*, *censo de censo de censo*, *cubo de cubo*.

The second plan was not to use a symbol for the unknown quantity itself, but to limit one's self in some way to simply indicating by a numeral the power of the unknown quantity. As long as powers of only one unknown quantity appeared in an equation, the writing of the index of its power was sufficient. In marking the first, second, third, etc., powers, only the numerals for "one," "two," "three," etc., were written down. A good illustration of this procedure is Chuquet's 10^2 for $10x^2$, 10^1 for $10x$, and 10^0 for 10 . We shall call this the "Index Plan." It was stressed by Chuquet, and passed through several stages of development in Bombelli, Stevin, and Girard. Then, after the introduction of special letters to designate one or more unknown quantities, and the use of literal coefficients, this notation was perfected by Hérigone and Hume; it finally culminated in the present-day form in the writings of Descartes, Wallis, and Newton.

295. *Early symbolisms*.—In elaborating the notations of powers according to the “Abbreviate Plan” cited in § 294, one or the other of two distinct principles was brought into play in combining the symbols of the lower powers to mark the higher powers. One was the additive principle of the Greeks in combining powers; the other was the multiplicative principle of the Hindus. Diophantus expressed the fifth power of the unknown by writing the symbols for x^2 and for x^3 , one following the other; the indices 2 and 3 were *added*. Now, Bhāskara writes his symbols for x^2 and x^3 in the same way, but lets the two designate, not x^5 , but x^6 ; the indices 2 and 3 are *multiplied*. This difference in designation prevailed through the Arabic period, the later Middle Ages in Europe down into the seventeenth century. It disappeared only when the notations of powers according to the “Abbreviate Plan” passed into disuse. References to the early symbolisms, mainly as exhibited in our accounts of individual authors, are as follows:

296. *Notations applied only to an unknown quantity, the base being omitted.*—As early as the fourteenth century, Oresme had the exponential concept, but his notation stands in historical isolation and does not constitute a part of the course of evolution of our modern exponential symbolism. We have seen that the earliest important steps toward the modern notation were taken by the Frenchman Nicolas Chuquet, the Italian Rafael Bombelli, the Belgian Simon Stevin, the Englishmen L. and T. Digges. Attention remains to be called to a symbolism very similar to that of the Digges, which was contrived by Pietro Antonio Cataldi of Bologna, in an algebra of 1610

and a book on roots of 1613. Cataldi wrote the numeral exponents in their natural upright position,¹ and distinguished them by crossing them out. His "5 $\cancel{3}$ via 8 $\cancel{4}$ fa 40 7" means $5x^3 \cdot 8x^4 = 40x^7$. His sign for x is \mathbf{X} . He made only very limited use of this notation.

The drawback of Stevin's symbolism lay in the difficulty of writing and printing numerals and fractions within the circle. Apparently as a relief from this cumbrousness, we find that the Dutch writer, Adrianus Romanus, in his *Ideae Mathematicae pars prima* (Antwerp, 1593), uses in place of the circle two rounded parentheses and vinculum above and below; thus, with him $1(\overline{45})$ stands for x^{45} . He uses this notation in writing his famous equation of the forty-fifth degree. Franciscus van Schooten² in his early publications and when he quotes from Girard uses the notation of Stevin.

A notation more in line with Chuquet's was that of the Swiss Joost Bürgi who, in a manuscript now kept in the library of the observatory at Pulkowa, used Roman numerals for exponents and wrote³

$$\begin{array}{cccccccc} \text{vi} & \text{v} & \text{iv} & \text{iii} & \text{ii} & \text{i} & & 0 \\ 8 + 12 - 9 + 10 + 3 + 7 - 4 & \text{for } 8x^6 + 12x^5 - 9x^4 + 10x^3 + 3x^2 + 7x - 4. \end{array}$$

In this notation Bürgi was followed by Nicolaus Reymers (1601) and J. Kepler.⁴ Reymers⁵ used also the cossic symbols, but chose R in place of \mathcal{R} ; occasionally he used a symbolism as in $25\text{IIII} + 20\text{II} - 10\text{III} - 8\text{I}$ for the modern $25x^4 + 20x^2 - 10x^3 - 8x$. We see that Cataldi, Romanus, Fr. van Schooten, Bürgi, Reymers, and Kepler belong in the list of those who followed the "Index Plan."

297. *Notations applied to any quantity, the base being designated.*—As long as literal coefficients were not used and numbers were not generally represented by letters, the notations of Chuquet, Bombelli,

¹ G. Wertheim, *Zeitschr. f. Math. u. Physik*, Vol. XLIV (1899), Hist.-Lit. Abteilung, p. 48.

² Francisci à Schooten, *De Organica conicarum sectionum . . . Tractatus* (Leyden, 1646), p. 96; Schooten, *Renati Descartes Geometria* (Frankfurt a./M., 1695), p. 359.

³ P. Treutlein in *Abhandlungen zur Geschichte der Mathematik*, Vol. II (Leipzig, 1879), p. 36, 104.

⁴ In his "De Figurarum regularium" in *Opera omnia* (ed. Ch. Frisch), Vol. V (1864), p. 104, Kepler lets the radius AB of a circle be 1 and the side BC of a regular inscribed heptagon be R . He says: "In hac proportionem continuitatem fingit, ut sicut est AB ad BC $1R$, sic sit $1R$ ad $1z$, et $1z$ as $1\mathcal{C}$, et $1\mathcal{C}$ ad $1zz$, et $1zz$ ad $1z\mathcal{C}$ et sic perpetuo, quod nos commodius signabimus per apices six, 1 , 1^1 , 1^{11} , 1^{111} , 1^{1111} , 1^V , 1^{VI} , 1^{VII} , etc."

⁵ N. Raimarus Ursus, *Aritmetica analytica* (Frankfurt a. O., 1601), Bl. C3v°. See J. Tropicke, *op. cit.*, Vol. II (2d ed., 1921), p. 122.

Stevin, and others were quite adequate. There was no pressing need of indicating the powers of a given number, say the cube of twelve; they could be computed at once. Moreover, as only the unknown quantity was raised to powers which could not be computed on the spot, why should one go to the trouble of writing down the base? Was it not sufficient to put down the exponent and omit the base?

Was it not easier to write 16^v than $16x^5$? But when through the innovations of Vieta and others, literal coefficients came to be employed, and when several unknowns or variables came to be used as in analytic geometry, then the omission of the base became a serious defect

in the symbolism. It will not do to write $15x^2 - 16y^2$ as $15^{ii} - 16^{ii}$. In watching the coming changes in notation, the reader will bear this problem in mind. Vieta's own notation of 1591 was clumsy: *D quadratum* or *D. quad.* stood for D^2 , *D cubum* for D^3 ; *A quadr.* for x^2 , *A* representing the unknown number.

In this connection perhaps the first writer to be mentioned is Luca Pacioli who in 1494 explained, as an alternative notation of powers, the use of *R* as a base, but in place of the exponent he employs an ordinal that is too large by unity (§ 136). Thus *R. 30^a* stood for x^{29} . Evidently Pacioli did not have a grasp of the exponential concept.

An important step was taken by Romanus¹ who uses letters and writes bases as well as the exponents in expressions like

$$A(4)+B(4)+4A(3) \text{ in } B+6A(2) \text{ in } B(2)+4A \text{ in } B(3)$$

which signifies

$$A^4+B^4+4A^3B+6A^2B^2+4AB^3.$$

A similar suggestion came from the Frenchman, Pierre Hérigone, a mathematician who had a passion for new notations. He wrote our a^3 as $a3$, our $2b^4$ as $2b4$, and our $2ba^2$ as $2ba2$. The coefficient was placed *before* the letter, the exponent *after*.

In 1636 James Hume² brought out an edition of the algebra of Vieta, in which he introduced a superior notation, writing down the base and elevating the exponent to a position above the regular line and a little to the right. The exponent was expressed in Roman

¹ See H. Bosmans in *Annales Société scient. de Bruxelles*, Vol. XXX, Part II (1906), p. 15.

² James Hume, *L'Algèbre de Viète, d'une méthode nouvelle claire et facile* (Paris 1636). See *Œuvres de Descartes* (ed. Charles Adam et P. Tannery), Vol. V, p. 504, 506-12.

numerals. Thus, he wrote A^{iii} for A^3 . Except for the use of the Roman numerals, one has here our modern notation. Thus, this Scotsman, residing in Paris, had almost hit upon the exponential symbolism which has become universal through the writings of Descartes.

298. *Descartes' notation of 1637.*—Thus far had the notation advanced before Descartes published his *Géométrie* (1637) (§ 191). Hérigone and Hume almost hit upon the scheme of Descartes. The only difference was, in one case, the position of the exponent, and, in the other, the exponent written in Roman numerals. Descartes expressed the exponent in Arabic numerals and assigned it an elevated position. Where Hume would write $5a^{\text{iv}}$ and Hérigone would write $5a_4$, Descartes wrote $5a^4$. From the standpoint of the printer, Hérigone's notation was the simplest. But Descartes' elevated exponent offered certain advantages in interpretation which the judgment of subsequent centuries has sustained. Descartes used positive integral exponents only.

299. *Did Stampioen arrive at Descartes' notation independently?*—Was Descartes alone in adopting the notation $5a^4$ or did others hit upon this particular form independently? In 1639 this special form was suggested by a young Dutch writer, Johan Stampioen.¹ He makes no acknowledgment of indebtedness to Descartes. He makes it appear that he had been considering the two forms 3a and a^3 , and had found the latter preferable.² Evidently, the symbolism a^3 was adopted by Stampioen after the book had been written; in the body of his book³ one finds *aaa*, *bbbb*, *fffff*, *gggggg*, but the exponential notation above noted, as described in his passage following the Preface, is not used. Stampioen uses the notation a^4 in some but not all parts of a controversial publication⁴ of 1640, on the solution of cubic equations, and directed against Waessenaer, a personal friend of Descartes. In view of the fact that Stampioen does not state the originators of any of the notations which he uses, it is not improbable that his a^3 was taken from Descartes, even though Stampioen stands out as an opponent of Descartes.⁵

¹ Johan Stampioen d'Jonghe, *Algebra ofte Nieuwe Stel-Regel* (The Hague, 1639). See his statement following the Preface.

² Stampioen's own words are: "*aaa*· dit is *a* drievoudich in hem selfs gemenichvuldicht. men soude oock daer voor konnen stellen 3a ofte better a^3 ."

⁵ *Œuvres de Descartes*, Vol. XII (1910), p. 32, 272-74.

300. *Notations used by Descartes before 1637.*—Descartes' indebtedness to his predecessors for the exponential notation has been noted. The new features in Descartes' notation, $5a^3$, $6ab^4$, were indeed very slight. What notations did Descartes himself employ before 1637?

In his *Opuscules de 1619–1621* he regularly uses German symbols as they are found in the algebra of Clavius; Descartes writes¹

$$“36-3z-6\mathcal{R} \text{ aequ. } 1\gamma,”$$

which means $36-3x^2-6x=x^3$. These *Opuscules* were printed by Foucher de Careil (Paris, 1859–60), but this printed edition contains corruptions in notation, due to the want of proper type. Thus the numeral 4 is made to stand for the German symbol \mathcal{R} ; the small letter γ is made to stand for the radical sign $\sqrt{}$. The various deviations from the regular forms of the symbols are set forth in the standard edition of Descartes' works. Elsewhere (§ 264) we call attention that Descartes² in a letter of 1640 used the Recordian sign of equality and the symbols N and C of Xylander, in the expression “ $1C-6N=40$.” Writing to Mersenne, on May 3, 1638, Descartes³ employed the notation of Vieta, “ $Aq+Bq+A \text{ in } B \text{ bis}$ ” for our a^2+b^2+2ab . In a posthumous document,⁴ of which the date of composition is not known, Descartes used the sign of equality found in his *Géométrie* of 1637, and P. Hérigone's notation for powers of given letters, as $b3x$ for b^3x , $a3z$ for a^3z . Probably this document was written before 1637. Descartes⁵ used once also the notation of Dounot (or Deidier, or Bar-le-Duc, as he signs himself in his books) in writing the equation $1C-9Q+13N \text{ eq. } \sqrt{288}-15$, but Descartes translates it into $y^2-9y^2+13y-12\sqrt{2}+15=0$.

301. *Use of Hérigone's notation after 1637.*—After 1637 there was during the seventeenth century still very great diversity in the exponential notation. Hérigone's symbolism found favor with some writers. It occurs in Florimond Debeaune's letter⁶ of September 25, 1638, to Mersenne in terms like $2y4$, $y3$, $2l2$ for $2y^4$, y^3 , and $2l^2$, re-

⁵ *Ibid.*, Vol. XII, p. 278.

⁶ *Ibid.*, Vol. V (1903), p. 516.

spectively. G. Schott¹ gives it along with older notations. Pietro Mengoli² uses it in expressions like $a^4 + 4a^3r + 6a^2r^2 + 4ar^3 + r^4$ for our $a^4 + 4a^3r + 6a^2r^2 + 4ar^3 + r^4$. The Italian Cardinal Michelangelo Ricci³ writes " AC_2 in CB_3 " for $\overline{AC}^2 \cdot \overline{CB}^3$. In a letter⁴ addressed to Ozanam one finds $b^4 + c^4 \curvearrowright a^4$ for $b^4 + c^4 = a^4$. Chr. Huygens⁵ in a letter of June 8, 1684, wrote $a^3 + aab$ for $a^3 + a^2b$. In the same year an article by John Craig⁶ in the *Philosophical Transactions* contains $a^3y + a^4$ for $a^3y + a^4$, but a note to the "Benevole Lector" appears at the end apologizing for this notation. Dechales⁷ used in 1674 and again in 1690 (along with older notations) the form $A^4 + 4A^3B + 6A^2B^2 + 4AB^3 + B^4$. A Swedish author, Andreas Spole,⁸ who in 1664–66 sojourned in Paris, wrote in 1692 an arithmetic containing expressions $3a^3 + 3a^2 - 2a - 2$ for $3a^3 + 3a^2 - 2a - 2$. Joseph Moxon⁹ lets " $A - B.(2)$ " stand for our $(A - B)^2$, also " $A - B.(3)$ " for our $(A - B)^3$. With the eighteenth century this notation disappeared.

302. *Later use of Hume's notation of 1636.*—Hume's notation of 1636 was followed in 1638 by Jean de Beaugrand¹⁰ who in an anonymous letter to Mersenne criticized Descartes and states that the equation $x^{IV} + 4x^{III} - 19x^{II} - 106x - 120$ has the roots $+5, -2, -3, -4$. Beaugrand also refers to Vieta and used vowels for the unknowns, as in " $A''' + 3AAB + ADP$ esgale a ZSS ." Again Beaugrand writes " $E''' \ominus - 13E - 12$ " for $x^3 - 13x - 12$, where the \ominus apparently designates the omission of the second term, as does \times with Descartes.

303. *Other exponential notations suggested after 1637.*—At the time of Descartes and the century following several other exponential notations were suggested which seem odd to us and which serve to

indicate how the science might have been retarded in its progress under the handicap of cumbrous notations, had such wise leadership as that of Descartes, Wallis, and Newton not been available. Rich. Balam¹ in 1653 explains a device of his own, as follows: "(2):3:, the Duplicat, or Square of 3, that is, 3×3 ; (4):2:, the Quadruplicat of 2, that is, $2 \times 2 \times 2 \times 2 = 16$." The Dutch J. Stampioen² in 1639 wrote $\square A$ for A^2 ; as early as 1575 F. Maurolycus³ used \square to designate the square of a line. Similarly, an Austrian, Johannes Caramuel,⁴ in 1670 gives " $\square 25$. est Quadratum Numeri 25. hoc est, 625." Huygens⁵ wrote "1000(3)10" for $1,000 = 10^3$, and "1024(10)2" for $1024 = 2^{10}$. A Leibnizian symbolism⁶ explained in 1710 indicates the cube of $AB+BC$ thus: $[3] (AB+BC)$; in fact, before this time, in 1695 Leibniz⁷ wrote $\boxed{m} \overline{y+a}$ for $(y+a)^m$.

304. Descartes preferred the notation aa to a^2 . Fr. van Schooten,⁸ in 1646, followed Descartes even in writing qq , xx rather than q^2 , x^2 , but in his 1649 Latin edition of Descartes' geometry he wrote preferably x^2 . The symbolism xx was used not only by Descartes, but also by Huygens, Rahn, Kersey, Wallis, Newton, Halley, Rolle, Euler—in fact, by most writers of the second half of the seventeenth and of the eighteenth centuries. Later, Gauss⁹ was in the habit of writing xx , and he defended his practice by the statement that x^2 did not take up less space than xx , hence did not fulfil the main object of a symbol. The x^2 was preferred by Leibniz, Ozanam, David Gregory, and Pascal.

305. The reader should be reminded at this time that the representation of positive integral powers by the repetition of the factors was suggested very early (about 1480) in the Dresden Codex C. 80 under the heading *Algorithmus de additis et minutis* where $x^2 = z$ and $x^{10} = zzzzz$; it was elaborated more systematically in 1553 by M.

Stifel (§ 156). One sees in Stifel the exponential notation applied, not to the unknown but to several different quantities, all of them known. Stifel understood that a quantity with the exponent zero had the value 1. But this notation was merely a suggestion which Stifel himself did not use further. Later, in Alsted's *Encyclopaedia*,¹ published at Herborn in Prussia, there is given an explanation of the German symbols for *radix*, *zensus*, *cubus*, etc.; then the symbols from Stifel, just referred to, are reproduced, with the remark that they are preferred by some writers. The algebra proper in the *Encyclopaedia* is from the pen of Johann Geysius² who describes a similar notation $2a$, $4aa$, $8aaa$, , $512aaaaaaa$ and suggests also the use of Roman numerals as indices, as in $2^I 4^II 8^III$ $512^{IX}cc$. Forty years after, Caramvel³ ascribes to Geysius the notation aaa for the cube of a , etc.

In England the repetition of factors for the designation of powers was employed regularly in Thomas Harriot. In a manuscript preserved in the library of Sion College, Nathaniel Torporley (1573–1632) makes strictures on Harriot's book, but he uses Harriot's notation.⁴ John Newton⁵ in 1654 writes $aaaaa$. John Collins writes in the *Philosophical Transactions* of 1668 $aaa - 3aa + 4a = N$ to signify $x^3 - 3x^2 + 4x = N$. Harriot's mode of representation is found again in the *Transactions*⁶ for 1684. Joseph Raphson⁷ uses powers of g up to g^{10} , but in every instance he writes out each of the factors, after the manner of Harriot.

306. The following curious symbolism was designed in 1659 by Samuel Foster⁸ of London:

							
q	c	qq	qc	cc	qqc	qcc	ccc
2	3	4	5	6	7	8	9

⁵ John Newton, *Institutio Mathematica or a Mathematical Institution* (London, 1654), p. 85.

⁶ *Philosophical Transactions*, Vol. XV–XVI (London, 1684–91), p. 247, 340.

⁷ Josepho Raphson, *Analysis Aequationum universalis* (London, 1702). [First edition, 1697.]

⁸ Samuel Foster, *Miscellanies, or Mathematical Lucubrations* (London, 1659), p. 10.

Foster did not make much use of it in his book. He writes the proportion

$$“ At AC : AR :: \overline{CD} : \overline{RP} , ”$$

which means

$$AC : AR = \overline{CD}^2 : \overline{RP}^2 .$$

An altogether different and unique procedure is encountered in the *Maandelykse Mathematische Liefhebberye* (1754–69), where $\sqrt[m]{\quad}$ signifies extracting the m th root, and $\text{———}\sqrt[m]{\quad}$ signifies raising to the m th power. Thus,

$$“ \frac{y^n}{b} = \sqrt[m]{ay} \quad ”$$

$$\frac{y^{mn}}{b^m} = ay \sqrt[m]{\quad} .$$

307. *Spread of Descartes' notation.*—Since Descartes' *Géométrie* appeared in Holland, it is not strange that the exponential notation met with prompter acceptance in Holland than elsewhere. We have already seen that J. Stampioen used this notation in 1639 and 1640. The great disciple of Descartes, Fr. van Schooten, used it in 1646, and in 1649 in his Latin edition of Descartes' geometry. In 1646 van Schooten indulges¹ in the unusual practice of raising some (but not all) of his coefficients to the height of exponents. He writes $x^3 - {}^3aax - {}^2a^3 \asymp 0$ to designate $x^3 - 3a^2x - 2a^3 = 0$. Van Schooten² does the same thing in 1657, when he writes 2ax for $2ax$. Before this Marini Ghetaldi³ in Italy wrote coefficients in a *low* position, as subscripts, as in the proportion,

$$“ ut AQ ad A_2 in B ita \frac{x}{y} ad m_2 + n , ”$$

which stands for $A^2 : 2AB = \frac{x}{y} : (2m + n)$. Before this Albert Girard⁴ placed the coefficients where we now write our exponents. I quote: “Soit un binome conjoint $B + C$. Son Cube era $B(B_q + C_q^3) + C(B_q^3 + C_q)$.” Here the cube of $B + C$ is given in the form corresponding

to $B(B^2+3C^2)+C(3B^2+C^2)$. Much later, in 1679, we find in the collected works of P. Fermat¹ the coefficients in an elevated position: 2D in A for $2DA$, 2R in E for $2RE$.

The Cartesian notation was used by C. Huygens and P. Mersenne in 1646 in their correspondence with each other,² by J. Hudde³ in 1658, and by other writers.

In England, J. Wallis⁴ was one of the earliest writers to use Descartes' exponential symbolism. He used it in 1655, even though he himself had been trained in Oughtred's notation.

The Cartesian notation is found in the algebraic parts of Isaac Barrow's⁵ geometric lectures of 1670 and in John Kersey's *Algebra*⁶ of 1673. The adoption of Descartes' a^4 in strictly algebraic operations and the retention of the older A_q , A_c for A^2 , A^3 in geometric analysis is of frequent occurrence in Barrow and in other writers. Seemingly, the impression prevailed that A^2 and A^3 suggest to the pupil the purely arithmetical process of multiplication, AA and AAA , but that the symbolisms A_q and A_c conveyed the idea of a geometric square and geometric cube. So we find in geometrical expositions the use of the latter notation long after it had disappeared from purely algebraic processes. We find it, for instance, in W. Whiston's edition of Tacquet's *Euclid*,⁷ in Sir Isaac Newton's *Principia*⁸ and *Opticks*,⁹ in B. Robins' *Tracts*,¹⁰ and in a text by K. F. Hauber.¹¹ In the *Philosophical Transactions* of London none of the pre-Cartesian notations for powers appear, except a few times in an article of 1714 from the pen of R. Cotes, and an occasional tendency to adhere to the primitive, but very

lucid method of repeating the factors, as aaa for a^3 . The modern exponents did not appear in any of the numerous editions of William Oughtred's *Clavis mathematicae*; the last edition of that popular book was issued in 1694 and received a new impression in 1702. On February 5, 1666–67, J. Wallis¹ wrote to J. Collins, when a proposed new edition of Oughtred's *Clavis* was under discussion: "It is true, that as in other things so in mathematics, fashions will daily alter, and that which Mr. Oughtred designed by great letters may be now by others designed by small; but a mathematician will, with the same ease and advantage, understand A_c or aaa ." As late as 1790 the Portuguese J. A. da Cunha² occasionally wrote A_q and A_c . J. Pell wrote r^2 and l^2 in a letter written in Amsterdam on August 7, 1645.³ J. H. Rahn's *Teutsche Algebra*, printed in 1659 in Zurich, contains for positive integral powers two notations, one using the Cartesian exponents, a^3 , x^4 , the other consisting of writing an Archimedean spiral (Fig. 96) between the base and the exponent on the right. Thus $a\odot 3$ signifies a^3 . This symbol is used to signify involution, a process which Rahn calls *involviren*. In the English translation, made by T. Brancker and published in 1668 in London, the Archimedean spiral is displaced by the omicron-sigma (Fig. 97), a symbol found among several English writers of textbooks, as, for instance, J. Ward,⁴ E. Hatton,⁵ Hammond,⁶ C. Mason,⁷ and by P. Ronayne⁸—all of whom use also Rahn's and Brancker's $\omega\omega$ to signify evolution. The omicron-sigma is found in Birks,⁹ it is mentioned by Saverien,¹⁰ who objects to it as being superfluous.

Of interest is the following passage in Newton's *Arithmetick*,¹¹ which consists of lectures delivered by him at Cambridge in the period 1669–85 and first printed in 1707: "Thus $\sqrt[4]{64}$ denotes 8; and $\sqrt[4]{3:64}$

denotes 4. . . . There are some that to denote the Square of the first Power, make use of g , and of c for the Cube, qq for the Biquadrate, and qc for the Quadrato-Cube, etc. . . . Others make use of other sorts of Notes, but they are now almost out of Fashion."

In the eighteenth century in England, when parentheses were seldom used and the vinculum was at the zenith of its popularity, bars were drawn horizontally and allowed to bend into a vertical

stroke¹ (or else were connected with a vertical stroke), as in $A \times B^n$ or in $\overline{a+b}^{\frac{m}{n}}$.

In France the Cartesian exponential notation was not adopted as early as one might have expected. In J. de Billy's *Nova geometriae clavis* (Paris, 1643), there is no trace of that notation; the equation $x+x^2=20$ is written " $1R+1Q \text{ aequatur } 20$." In Fermat's edition² of Diophantus of 1670 one finds in the introduction $1QQ+4C+10Q+20N+1$ for $x^4+4x^3+10x^2+20x+1$. But in an edition of the works of Fermat, brought out in 1679, after his death, the algebraic notation of Vieta which he had followed was discarded in favor of the exponents of Descartes.³ B. Pascal⁴ made free use of positive integral exponents in several of his papers, particularly the *Potestatum numericarum summa* (1654).

In Italy, C. Renaldini⁵ in 1665 uses both old and new exponential notations, with the latter predominating.

308. *Negative, fractional, and literal exponents.*—Negative and fractional exponential notations had been suggested by Oresme, Chuquet, Stevin, and others, but the modern symbolism for these is due to Wallis and Newton. Wallis⁶ in 1656 used positive integral exponents and speaks of negative and fractional "indices," but he does not actually write a^{-1} for $\frac{1}{a}$, $a^{\frac{1}{2}}$ for \sqrt{a} . He speaks of the series

$\frac{1}{\sqrt{1}}, \frac{1}{\sqrt{2}}, \frac{1}{\sqrt{3}}$, etc., as having the "index $-\frac{1}{2}$." Our modern notation involving fractional and negative exponents was formally introduced a dozen years later by Newton¹ in a letter of June 13, 1676, to Oldenburg, then secretary of the Royal Society of London, which explains the use of negative and fractional exponents in the statement, "Since algebraists write a^2, a^3, a^4 , etc., for $aa, aaa, aaaa$, etc., so I write a^1, a^2, a^3 , for $\sqrt{a}, \sqrt[3]{a}, \sqrt[4]{a}$; and I write a^{-1}, a^{-2}, a^{-3} , etc., for $\frac{1}{a}, \frac{1}{aa}, \frac{1}{aaa}$, etc." He exhibits the general exponents in his binomial formula first announced in that letter:

$$[P+PQ]^m = P^m + \frac{m}{n} A Q + \frac{m-n}{2n} B Q^2 + \frac{m-2n}{3n} C Q^3 + \frac{m-3n}{4n} D Q^4 + \dots,$$

where $A = P^{\frac{m}{n}}$, $B = \frac{m}{n} P^{\frac{m}{n}} Q$, etc., and where $\frac{m}{n}$ may represent any real and rational number. It should be observed that Newton wrote here literal exponents such as had been used a few times by Wallis,² in 1657, in expressions like $\sqrt[d]{R^d} = R$, $AR^m \times AR^n = A^2 R^{m+n}$, which arose in the treatment of geometric progression. Wallis gives also the division $AR^m)AR^{m+n}(R^n$. Newton³ employs irrational exponents in his letter to Oldenburg of the date October 24, 1676, where he writes $\sqrt{x^2} + x\sqrt[7]{x^2} = y$. Before Wallis and Newton, Vieta indicated general exponents a few times in a manner almost rhetorical;⁴ his

$$A \text{ potestas} + \frac{E \text{ potestate} - A \text{ potesta}}{E \text{ gradui} + A \text{ gradu}} \text{ in } A \text{ gradum}$$

is our

$$x^m + \frac{y^m - x^m}{y^n + x^n} \cdot x^n,$$

the two distinct general powers being indicated by the words *potestas* and *gradus*. Johann Bernoulli⁵ in 1691–92 still wrote $3 \square \sqrt[3]{ax+xx}$ for

⁵ Iohannis I Bernoulli, *Lectiones de calculo differentialium . . .* von Paul Schafheitlin. Separatabdruck aus den *Verhandlungen der Naturforschenden Gesellschaft in Basel*, Vol. XXXIV, 1922.

$3\sqrt[3]{(ax+x^2)^2}$, $4C\sqrt[4]{yx+xx}$ for $4\sqrt[4]{(yx+x^2)^3}$, $5QQ\sqrt[5]{ayx+x^3+zyx}$ for $5\sqrt[5]{(ayx+x^3+zyx)^4}$. But fractional, negative, and general exponents were freely used by D. Gregory¹ and were fully explained by W. Jones² and by C. Reyneau.³ Reyneau remarks that this theory is not explained in works on algebra.

309. *Imaginary exponents*.—The further step of introducing imaginary exponents is taken by L. Euler in a letter to Johann Bernoulli,⁴ of October 18, 1740, in which he announces the discovery of the formula $e^{+x\sqrt{-1}}+e^{-x\sqrt{-1}}=2\cos x$, and in a letter to C. Goldbach,⁵ of December 9, 1741, in which he points out as a curiosity that the fraction $\frac{2^{+1\sqrt{-1}}+2^{-1\sqrt{-1}}}{2}$ is nearly equal to $\frac{1}{3}$. The first appearance of imaginary exponents in print is in an article by Euler in the *Miscellanea Berolinensia* of 1743 and in Euler's *Introductio in analysin* (Lausannae, 1747), Volume I, page 104, where he gives the all-important formula $e^{+v\sqrt{-1}}=\cos v+\sqrt{-1}\sin v$.

310. At an earlier date occurred the introduction of variable exponents. In a letter of 1679, addressed to C. Huygens, G. W. Leibniz⁶ discussed equations of the form $x^x-x=24$, $x^x+z^x=b$, $x^x+z^z=c$. On May 9, 1694, Johann Bernoulli⁷ mentions expressions of this sort in a letter to Leibniz who, in 1695, again considered exponentials in the *Acta eruditorum*, as did also Johann Bernoulli in 1697.

311. Of interest is the following quotation from a discussion by T. P. Nunn, in the *Mathematical Gazette*, Volume VI (1912), page 255, from which, however, it must not be inferred that Wallis actually wrote down fractional and negative exponents: "Those who are acquainted with the work of John Wallis will remember that he invented negative and fractional indices in the course of an investigation into methods of evaluating areas, etc. He had

discovered that if the ordinates of a curve follow the law $y=kx^n$ its area follows the law $A=\frac{1}{n+1} \cdot kx^{n+1}$, n being (necessarily) a positive integer. This law is so remarkably simple and so powerful as a method that Wallis was prompted to inquire whether cases in which the ordinates follow such laws as $y=\frac{k}{x^n}$, $y=k\sqrt[n]{x}$ could not be brought within its scope. He found that this extension of the law would be possible if $\frac{k}{x^n}$ could be written kx^{-n} , and $k\sqrt[n]{x}$ as $kx^{\frac{1}{n}}$. From this, from numerous other historical instances, and from general psychological observations, I draw the conclusion that extensions of notation should be taught because and when they are needed for the attainment of some practical purpose, and that logical criticism should come after the suggestion of an extension to assure us of its validity."

312. *Notation for principal values.*—When in the early part of the nineteenth century the multiplicity of values of a^n came to be studied, where a and n may be negative or complex numbers, and when the need of defining the principal values became more insistent, new notations sprang into use in the exponential as well as the logarithmic theories. A. L. Cauchy¹ designated all the values that a^n may take, for given values of a and n [$a \neq 0$], by the symbol $((a))^x$, so that $((a))^x = e^{xla} \cdot e^{2kx\pi i}$, where l means the tabular logarithm of $|a|$, $e=2.718 \dots$, $\pi=3.141 \dots$, $k=0, \pm 1, \pm 2, \dots$. This notation is adopted by O. Stolz and J. A. Gmeiner² in their *Theoretische Arithmetik*.

Other notations sprang up in the early part of the last century. Martin Ohm elaborated a general exponential theory as early as 1821 in a Latin thesis and later in his *System der Mathematik* (1822–33).³ In a^x , when a and x may both be complex, $\log a$ has an infinite number of values. When, out of this infinite number some particular value of $\log a$, say α , is selected, he indicates this by writing $(a||\alpha)$. With this understanding he can write $x \log a + y \log a = (x+y) \log a$, and consequently $a^x \cdot a^y = a^{x+y}$ is a *complete* equation, that is, an equation in which both sides have the same number of values, representing exactly the same expressions. Ohm did not introduce the particular value of a^x which is now called the "principal value."

in which each *post* means all which follows is to be placed on the top of it. Thus:¹

$$x|a|b|c|d = x^{a|b|c|d} = x^{a^{b|c|d}} = x^{a^{b^c|d}} = x^{a^{b^c d}}.$$

When the base and the successive exponents are all alike, say a , Woepecke² used the symbol $\overset{m}{a}$ for $((a^a)^{a^{\cdot\cdot}})^a$, and $\overset{m}{a}$ for $a^{(a^{\cdot\cdot(a^a)})}$, where m indicates the number of repetitions of a . He extended this notation to cases where a is real or imaginary, not zero, and m is a positive or negative integer, or zero. A few years later J. W. L. Glaisher suggested still another notation for complicated exponents, namely,

$a \uparrow^{\frac{1}{n}} x^n + \frac{b}{x^n} \uparrow$, the arrows merely indicating that the quantity between

them is to be raised so as to become the exponent of a . Glaisher prefers this to " a Exp. u " for a^u . Harkness and Morley³ state, "It is usual to write $\exp(z) = e^z$, when z is complex." The contraction "exp" was recommended by a British Committee (§ 725) in 1875, but was ignored in the suggestions of 1916, issued by the Council of the London Mathematical Society. G. H. Bryan stresses the usefulness of this symbol.⁴

Another notation was suggested by H. Schubert. If a^a is taken as an exponent of a , one obtains $a^{(a^a)}$ or a^{a^a} , and so on. Schubert designates the result by $(a; b)$, indicating that a has been thus written b times.⁵ For the expression $(a; b)^{(a; c)}$ there has been adopted the sign $(a; b+c)$, so that $(a; b)^{(a; c)} = (a; c+1)^{(a; b-1)}$.

314. *D. F. Gregory*⁶ in 1837 made use of the sign $(+)^r$, r an integer, to designate the repetition of the operation of multiplication. Also, $(+a^2)^{\frac{1}{2}} = +^{\frac{1}{2}}(a^2)^{\frac{1}{2}} = +^{\frac{1}{2}}a$, where the $+^{\frac{1}{2}}$ "will be different, according as we suppose the $+$ to be equivalent to the operation repeated an even or an odd number of times. In the former case it will be equal to $+$, in the latter to $-$. And generally, if we raise $+a$ to any power m , whether whole or fractional, we have $(+a)^m = +^m a^m$ So long as

m is an integer, rm is an integer, and $+^m a^m$ has only one value; but if m be a fraction of the form $\frac{p}{q}$, $+^{\frac{p}{q}}$ will acquire different values, according as we assign different values to $r \dots \sqrt[q]{(-a)} \times \sqrt[q]{(-a)} = \sqrt[q]{(+a^2)} = \sqrt[q]{(+)} \sqrt[q]{(a^2)} = -a$; for in this case we know how the $+$ has been derived, namely from the product $- \cdot - = +$, or $-^2 = +$, which of course gives $+^{\frac{1}{2}} = -$, there being here nothing indeterminate about the $+$. It was in consequence of sometimes tacitly assuming the existence of $+$, and at another time neglecting it, that the errors in various trigonometrical expressions arose; and it was by the introduction of the factor $\cos 2r\pi + (-)^r \sin 2r\pi$ (which is equivalent to $+^r$) that Poincot established the formulae in a more correct and general shape." Gregory finds " $\sin (+^{\frac{p}{q}}c) = +^{\frac{p}{q}} \sin c$."

A special notation for the positive integral powers of an imaginary root r of $x^{n-1} + x^{n-2} + \dots + x + 1 = 0$, n being an odd prime, is given by Gauss;¹ to simplify the typesetting he designates r , rr , r^3 , etc., by the symbols [1], [2], [3], etc.

315. *Conclusions.*—There is perhaps no symbolism in ordinary algebra which has been as well chosen and is as elastic as the Cartesian exponents. Descartes wrote a^3 , x^4 ; the extension of this to general exponents a^n was easy. Moreover, the introduction of fractional and negative numbers, as exponents, was readily accomplished. The irrational exponent, as in $a^{\sqrt{2}}$, found unchallenged admission. It was natural to try exponents in the form of pure imaginary or of complex numbers (L. Euler, 1740). In the nineteenth century valuable interpretations were found which constitute the general theory of b^n where b and n may both be complex. Our exponential notation has been an aid for the advancement of the science of algebra to a degree that could not have been possible under the old German or other early notations. Nowhere is the importance of a good notation for the rapid advancement of a mathematical science exhibited more forcibly than in the exponential symbolism of algebra.

SIGNS FOR ROOTS

316. *Early forms.*—Symbols for roots appear very early in the development of mathematics. The sign $\sqrt{\quad}$ for square root occurs in two Egyptian papyri, both found at Kahun. One was described by F. L.

¹ C. F. Gauss, *Disquisitiones arithmeticae* (Leipzig, 1801), Art. 342; *Werke*, Vol. I (1863), p. 420.

Griffith¹ and the other by H. Schack-Schackenburg.² For Hindu signs see §§ 107, 108, 112; for Arabic signs see § 124.

317. *General statement.*—The principal symbolisms for the designation of roots, which have been developed since the influx of Arabic learning into Europe in the twelfth century, fall under four groups having for their basic symbols, respectively, R (*radix*), l (*latus*), the sign $\sqrt{}$, and the fractional exponent.

318. *The sign R ; first appearance.*—In a translation³ from the Arabic into Latin of a commentary of the tenth book of the *Elements* of Euclid, the word *radix* is used for “square root.” The sign R came to be used very extensively for “root,” but occasionally it stood also for the first power of the unknown quantity, x . The word *radix* was used for x in translations from Arabic into Latin by John of Seville and Gerard of Cremona (§ 290). This double use of the sign R for x and also for square root is encountered in Leonardo of Pisa (§§ 122, 292)⁴ and Luca Pacioli (§§ 135–37, 292).

Before Pacioli, the use of R to designate square root is also met in a correspondence that the German astronomer Regiomontanus (§ 126)⁵ carried on with Giovanni Bianchini, who was court astronomer at Ferrara in Italy, and with Jacob von Speier, a court astronomer at Urbino (§ 126).

In German manuscripts referred to as the Dresden MSS C. 80, written about the year 1480, and known to have been in the hands of J. Widman, H. Grammateus, and Adam Riese, there is a sign consisting of a small letter, with a florescent stroke attached (Fig. 104). It has been interpreted by some writers as a letter r with an additional stroke. Certain it is that in Johann Widman's arithmetic of 1489 occurs the crossed capital letter R , and also the abbreviation *ra* (§ 293).

Before Widman, the Frenchman Chuquet had used R for “root”

⁴ *Scritti di Leonardo Pisano* (ed. B. Boncompagni), Vol. II (Rome, 1862), “La practica geometriae,” p. 209, 231. The word *radix*, meaning x , is found also in Vol. I, p. 407.

⁵ M. Curtze, “Der Briefwechsel Riomantan's, etc.,” *Abhandlungen zur Geschichte der mathematischen Wissenschaften*, Vol. XII (Leipzig, 1902), p. 234, 318.

in his manuscript, *Le Triparty* (§ 130). He¹ indicates R^2 16. as 4, " R^4 . 16. si est . 2.," " R^5 . 32. si est . 2."

319. *Sixteenth-century use of R.*—The different uses of R . made in Pacioli's *Summa* (1494, 1523) are fully set forth in §§ 134–38. In France, De la Roche followed Chuquet in the use of R . (§ 132). The symbol appears again in Italy in Ghaligai's algebra (1521), and in later editions (§ 139), while in Holland it appeared as early as 1537 in the arithmetic of Giel Van der Hoecke (§ 150) in expressions like "Item wildi aftrecken $R \frac{1}{5}$ van $R \frac{4}{5}$ resi $R \frac{1}{5}$ "; i.e., $\sqrt[5]{\frac{4}{5}} - \sqrt[5]{\frac{1}{5}} = \sqrt[5]{\frac{3}{5}}$. The employment of R in the calculus of radicals by Cardan is set forth in §§ 141, 199. A promiscuous adoption of different notations is found in the algebra of Johannes Scheubel (§§ 158, 159) of the University of Tübingen. He used Widman's abbreviation *ra*, also the sign $\sqrt{}$; he indicates cube root by *ra. cu.* or by $\sqrt[3]{}$, fourth root by *ra. ra.* or by $\sqrt[4]{}$. He suggests a notation of his own, of which he makes no further use, namely, *radix se.*, for cube root, which is the abbreviation of *radix secundae quantitatis*. As the sum "*ra. 15 ad ra. 17*" he gives "*ra. col. 32 + \sqrt{1020}*," i.e., $\sqrt{15} + \sqrt{17} = \sqrt{32 + \sqrt{1020}}$. The *col.*, *collecti*, signifies here aggregation.

Nicolo Tartaglia in 1556 used R extensively and also parentheses (§§ 142, 143). Francis Maurolycus² of Messina in 1575 wrote "*r. 18*" for $\sqrt{18}$, "*r. v. 6 m. r 7\frac{1}{2}*" for $\sqrt{6 - \sqrt{7\frac{1}{2}}}$. Bombelli's radical notation is explained in § 144. It thus appears that in Italy the R had no rival during the sixteenth century in the calculus of radicals. The only variation in the symbolism arose in the marking of the order of the radical and in the modes of designation of the aggregation of terms that were affected by R .

320. In Spain³ the work of Marco Aurel (1552) (§ 204) employs the signs of Stifel, but Antich Rocha, adopting the Italian abbreviations in adjustment to the Spanish language, lets, in his *Arithmetica* of 1564, "*15 Mas ra. q. 50 Mas ra. q. 27 Mas ra. q. 6*" stand for $15 + \sqrt{50} + \sqrt{27} + \sqrt{6}$. A few years earlier, J. Perez de Moya, in his *Aritmetica practica y speculativa* (1562), indicates square root by *r*,

¹ *Le Triparty en la science des nombres par Maistre Nicolas Chuquet Parisien ...* par M. Aristide Marre in Boncompagni's *Bullettino*, Vol. XIII, p. 655; (reprint, Rome, 1881), p. 103.

² *D. Francisci Maurolyci, Abbatis Messanensis, Opuscula mathematica* (Venice, 1575), p. 144.

³ Our information on these Spanish authors is drawn partly from Julio Rey Pastor, *Los Matemáticos españoles de siglo XVI* (Oviedo, 1913), p. 42.

cube root by *rrr*, fourth root by *rr*, marks powers by *co.*, *ce.*, *cu.*, *c. ce.*, and "plus" by *p*, "minus" by *m*, "equal" by *eq*.

In Holland, Adrianus Romanus¹ used a small *r*, but instead of *v* wrote a dot to mark a root of a binomial or polynomial; he wrote

r bin. 2+r bin. 2+r bin. 2+r 2. to designate $\sqrt{2+\sqrt{2+\sqrt{2+\sqrt{2}}}}$.

In Tartaglia's arithmetic, as translated into French by Gosselin² of Caen, in 1613, one finds the familiar *R cu* to mark cube root. A modification was introduced by the Scotsman James Hume,³ residing in Paris, who in his algebra of 1635 introduced Roman numerals to indicate the order of the root (§ 190). Two years later, the French text by Jacques de Billy⁴ used *RQ*, *RC*, *RQC* for $\sqrt{}$, $\sqrt[3]{}$, $\sqrt[4]{}$, respectively.

321. *Seventeenth-century use of R.*—During the seventeenth century, the symbol *R* lost ground steadily but at the close of the century it still survived; it was used, for instance, by Michael Rolle⁵ who employed the signs $2+R.-121.$ to represent $2+\sqrt{-121}$, and *R. trin. 6aabb-9a⁴b-b³* to represent $\sqrt{6a^2b^2-9a^4b-b^3}$. In 1690 H. Vitalis⁶ takes *R₂* to represent *secunda radix*, i.e., the radix next after the square root. Consequently, with him, as with Scheubel, 3. *R. 2** 8, meant $3\sqrt[3]{8}$, or 6.

The sign *R* or *R*, representing a radical, had its strongest foothold in Italy and Spain, and its weakest in England. With the close of the seventeenth century it practically passed away as a radical sign; the symbol $\sqrt{}$ gained general ascendancy. Elsewhere it will be pointed out in detail that some authors employed *R* to represent the unknown *x*. Perhaps its latest regular appearance as a radical sign is in the Spanish text of Perez de Moya (§ 320), the first edition of which appeared in 1562. The fourteenth edition was issued in 1784; it still gave *rrr* as signifying cube root, and *rr* as fourth root. Moya's book offers a most striking example of the persistence for centuries of old and clumsy notations, even when far superior notations are in general use.

⁶ *Lexicon mathematicum ... authore Hieronymo Vitali* (Rome, 1690), art. "Algebra."

322. *The sign l.*—The Latin word *latus* ("side of a square") was introduced into mathematics to signify root by the Roman surveyor Junius Nipsus,¹ of the second century A.D., and was used in that sense by Martianus Capella,² Gerbert,³ and by Plato of Tivoli in 1145, in his translation from the Arabic of the *Liber embadorum* (§ 290). The symbol *l* (*latus*) to signify root was employed by Peter Ramus⁴ with whom "*l* 27 *ad l* 12" gives "*l* 75," i.e., $\sqrt{27} + \sqrt{12} = \sqrt{75}$; "*ll* 32 *de ll* 162" gives "*ll* 2," i.e., $\sqrt[4]{32}$ from $\sqrt[4]{162} = \sqrt[4]{2}$. Again,⁵ "*8-l* 20 *in* 2 *quotus est* (*4-l* 5)." means $8 - \sqrt{20}$, divided by 2, gives the quotient $4 - \sqrt{5}$. Similarly,⁶ "*lr*. *ll* 112-*l* 76" meant $\sqrt{\sqrt{112} - \sqrt{76}}$; the *r* signifying here *residua*, or "remainder," and therefore *lr*. signified the square root of the binomial difference.

In the 1592 edition⁷ of Ramus' arithmetic and algebra, edited by Lazarus Schoner, "*lc* 4" stands for $\sqrt[3]{4}$, and "*l* *bq* 5" for $\sqrt[4]{5}$, in place of Ramus' "*ll* 5." Also, $\sqrt{2}$. $\sqrt{3} = \sqrt{6}$, $\sqrt{6} \div \sqrt{2} = \sqrt{3}$ is expressed thus:⁸

"Esto multiplicandum l_2 per l_3 factus erit l 6.

$$\begin{array}{rcl} l\ 2. & & l\ 6 \\ l\ 3. & & l\ 2 \left(l\ 3 \right. \\ \hline & & l\ 6. \end{array}$$

It is to be noted that with Schoner the *l* received an extension of meaning, so that *5l* and *l5*, respectively, represent $5x$ and $\sqrt{5}$, the *l* standing for the first power of the unknown quantity when it is not

followed by a number (see also § 290). A similar change in meaning resulting from reversing the order of two symbols has been observed in Pacioli in connection with R (§§ 136, 137) and in A. Girard in connection with the circle of Stevin (§ 164). The double use of the sign l , as found in Schoner, is explained more fully by another pupil of Ramus, namely, Bernardus Salignacus (§ 291).

Ramus' l was sometimes used by the great French algebraist Francis Vieta who seemed disinclined to adopt either R or $\sqrt{}$ for indicating roots (§ 177).

This use of the letter l in the calculus of radicals never became popular. After the invention of logarithms, this letter was needed to mark logarithms. For that reason it is especially curious that Henry Briggs, who devoted the latter part of his life to the computation and the algorithm of logarithms, should have employed l in the sense assigned it by Ramus and Vieta. In 1624 Briggs used $l, l_{(3)}, ll$ for square, cube, and fourth root, respectively. "Sic $l_{(3)} 8$ [i.e., $\sqrt[3]{8}$], latus cubicum Octonarii, id est 2. sic l bin $2 + l 3$. [i.e., $\sqrt{2 + \sqrt{3}}$] latus binomii $2 + l3$." Again, " $ll 85\frac{1}{3}$ [i.e., $\sqrt[4]{85\frac{1}{3}}$]. Latus $85\frac{1}{3}$ est $9^{237604307}$, et huius lateris latus est $3^{032234274}$. cui numero aequatur $ll 85\frac{1}{3}$."¹

323. *Napier's line symbolism.*—John Napier² prepared a manuscript on algebra which was not printed until 1839. He made use of Stifel's notation for radicals, but at the same time devised a new scheme of his own. "It is interesting to notice that although Napier invented an excellent notation of his own for expressing roots, he did not make use of it in his algebra, but retained the cumbrous, and in some cases ambiguous notation generally used in his day. His notation was derived from this figure

1	2	3
4	5	6
7	8	9

in the following way: \square prefixed to a number means its square root, \square its fourth root, \square its fifth root, \uparrow its ninth root, and so on, with extensions of obvious kinds for higher roots."³

¹ Henry Briggs, *Arithmetica logarithmica* (London, 1624), Introduction.

² *De Arte Logistica Joannis Naperi Merchistonii Baronis Libri qui supersunt* (Edinburgh, 1839), p. 84.

THE SIGN $\sqrt{}$

324. *Origin of $\sqrt{}$.*—This symbol originated in Germany. L. Euler guessed that it was a deformed letter r , the first letter in *radix*.¹ This opinion was held generally until recently. The more careful study of German manuscript algebras and the first printed algebras has convinced Germans that the old explanation is hardly tenable; they have accepted the a priori much less probable explanation of the evolution of the symbol from a dot. Four manuscript algebras have been available for the study of this and other questions.

The oldest of these is in the Dresden Library, in a volume of manuscripts which contains different algebraic treatises in Latin and one in German.² In one of the Latin manuscripts (see Fig. 104, A7), probably written about 1480, dots are used to signify root extraction. In one place it says: "In extraccione radicis quadrati alicuius numeri preponatur numero vnus punctus. In extraccione radicis quadrati radicis quadrati prepone numero duo puncta. In extraccione cubici radicis alicuius numeri prepone tria puncta. In extraccione cubici radicis alicuius radicis cubici prepone 4 puncta."³ That is, one dot (·) placed before the radicand signifies square root; two dots (..) signify the square root of the square root; three dots (...) signify cube root; four dots (....), the cube root of the cube root or the ninth root. Evidently this notation is not a happy choice. If one dot meant square root and two dots meant square root of square root (i.e., $\sqrt{\sqrt{}}$), then three dots should mean square root of square root of square root, or eighth root. But such was not actually the case; the three dots were made to mean cube root, and four dots the ninth root. What was the origin of this dot-system? No satisfactory explanation has been found. It is important to note that this Dresden manuscript was once in the possession of Joh. Widman, and that Adam Riese, who in 1524 prepared a manuscript algebra of his own, closely followed the Dresden algebra.

325. The second document is the Vienna MS⁴ No. 5277, *Regule-*

¹ L. Euler, *Institutiones calculi differentialis* (1775), p. 103, art. 119; J. Tropfke, *op. cit.*, Vol. II (2d ed., 1921), p. 150.

⁴ C. J. Gerhardt, *Monatsberichte Akad.* (Berlin, 1867), p. 46; *ibid.* (1870), p. 143-47; Cantor, *op. cit.*, Vol. II (2d ed., 1913), p. 240, 424.

Cose-ucl Algrebre-. It contains the passage: "Quum \int assimiletur radici de radice punctus deleatur de radice, \int in se ducatur et remanet adhuc inter se aequalia"; that is, "When $x^2 = \sqrt{x}$, erase the point before the x and multiply x^2 by itself, then things equal to each other are obtained." In another place one finds the statement, *per punctum intellige radicem*—"by a point understand a root." But no dot is actually used in the manuscript for the designation of a root.

The third manuscript is at the University of Göttingen, Codex Gotting. Philos. 30. It is a letter written in Latin by Initius Algebras,¹ probably before 1524. An elaboration of this manuscript was made in German by Andreas Alexander.² In it the radical sign is a heavy point with a stroke of the pen up and bending to the right, thus \int . It is followed by a symbol indicating the index of the root; $\int\int$ indicates square root; $\int c^3$, cube root; $\int cc^9$, the ninth root, etc. Moreover, $\int cs[8 + \int 22]$ stands for $\sqrt[cs]{8 + \sqrt{22}}$, where *cs* (i.e., *communis*) signifies the root of the binomial which is designated as one quantity, by lines, vertical and horizontal. Such lines are found earlier in Chuquet (§ 130). The \int , indicating the square root of the binomial, is placed as a subscript after the binomial. Calling these two lines a "gnomon," M. Curtze adds the following:

"This gnomon has here the signification, that what it embraces is not a length, but a power. Thus, the simple 8 is a length or simple number, while $\int 8$ is a square consisting of eight areal units whose linear unit is $\int\int 8$. In the same way $\int c^3 8$ would be a cube, made up of 8 cubical units, of which $\int c^3 8$ is its side, etc. A double point, with the tail attached to the last, signifies always the root of the root. For example, $\int c^3 \int 88$ would mean the cube root of the cube root of 88. It is identical with $\int cc^9 88$, but is used only when the radicand is a so-called median [*Mediale*] in the Euclidean sense."³

326. The fourth manuscript is an algebra or *Coss* completed by Adam Riese⁴ in 1524; it was not printed until 1892. Riese was familiar with the small Latin algebra in the Dresden collection, cited above;

¹ Initius Algebras: *Algebrae Arabis Arithmetici viri clarrissimi Liber ad Ylem geometram magistrum suum*. This was published by M. Curtze in *Abhandlungen zur Geschichte der mathematischen Wissenschaften*, Heft XIII (1902), p. 435-611. Matters of notation are explained by Curtze in his introduction, p. 443-48.

² G. Eneström, *Bibliotheca mathematica* (3d ser.), Vol. III (1902), p. 355-60.

³ M. Curtze, *op. cit.*, p. 444.

⁴ B. Berlet, *Adam Riese, sein Leben, seine Rechenbücher und seine Art zu rechnen; die Coss von Adam Riese* (Leipzig-Frankfurt a/M., 1892).

he refers also to Andreas Alexander.¹ For indicating a root, Riese does not use the dot, pure and simple, but the dot with a stroke attached to it, though the word *punct* ("point") occurs. Riese says: "Ist, so 3 vergleicht wird $\sqrt{\cdot}$ vom radix, so mal den 3 in sich multipliciren vnnd das punct vor dem Radix aussleschn."² This passage has the same interpretation as the Latin passage which we quoted from the Vienna manuscript.

We have now presented the main facts found in the four manuscripts. They show conclusively that the dot was associated as a symbol with root extraction. In the first manuscript, the dot actually appears as a sign for roots. The dot does not appear as a sign in the second manuscript, but is mentioned in the text. In the third and fourth manuscripts, the dot, pure and simple, does not occur for the designation of roots; the symbol is described by recent writers as a dot with a stroke or tail attached to it. The question arises whether our algebraic sign $\sqrt{\cdot}$ took its origin in the dot. Recent German writers favor that view, but the evidence is far from conclusive. Johannes Widman, the author of the *Rechnung* of 1489, was familiar with the first manuscript which we cited. Nevertheless he does not employ the dot to designate root, easy as the symbol is for the printer. He writes down *R* and *ra*. Christoff Rudolff was familiar with the Vienna manuscript which uses the dot with a tail. In his *Coss* of 1525 he speaks of the *Punkt* in connection with root symbolism, but uses a mark with a very short heavy downward stroke (almost a point), followed by a straight line or stroke, slanting upward (see Fig. 59). As late as 1551, Scheubel,³ in his printed *Algebra*, speaks of points. He says: "Solent tamen multi, et bene etiam, has desideratas radices, suis punctis cū linea quadam a dextro latere ascendente, notare. . . ." ("Many are accustomed, and quite appropriately, to designate the desired roots by points, from the right side of which there ascends a kind of stroke.") It is possible that this use of "point" was technical, signifying "sign for root," just as at a later period the expression "decimal point" was used even when the symbol actually written down to mark a decimal fraction was a comma. It should be added that if Rudolff looked upon his radical sign as really a dot, he would have been less likely to have used the dot again for a second purpose in his radical symbolism, namely, for the purpose of designating that

¹ B. Berlet, *op. cit.*, p. 29, 33.

² C. I. Gerhardt, *op. cit.* (1870) p. 151.

³ J. Scheubel, *Algebra compendiosa* (Paris, 1551), fol. 25B. Quoted from J. Tropfke, *op. cit.*, Vol. II (2d ed., 1921), p. 149.

the root extraction must be applied to two or more terms following the $\sqrt{}$; this use of the dot is shown in § 148. It is possible, perhaps probable, that the symbol in Rudolff and in the third and fourth manuscripts above referred to is not a point at all, but an *r*, the first letter in *radix*. That such was the understanding of the sixteenth-century Spanish writer, Perez de Moya (§ 204), is evident from his designations of the square root by *r*, the fourth root by *rr*, and the cube root by *rrr*. It is the notation found in the first manuscript which we cited, except that in Moya the *r* takes the place of the dot; it is the notation of Rudolff, except that the sign in Rudolff is not a regularly shaped *r*. In this connection a remark of H. Wieleitner is pertinent: "The dot appears at times in manuscripts as an abbreviation for the syllable *ra*. Whether the dot used in the Dresden manuscript represents this normal abbreviation for *radix* does not appear to have been specially examined."¹

The history of our radical sign $\sqrt{}$, after the time of Rudolff, relates mainly to the symbolisms for indicating (1) the index of the root, (2) the aggregation of terms when the root of a binomial or polynomial is required. It took over a century to reach some sort of agreement on these points. The signs of Christoff Rudolff are explained more fully in § 148. Stifel's elaboration of the symbolism of Andreas Alexander as given in 1544 is found in §§ 153, 155. Moreover, he gave to the $\sqrt{}$ its modern form by making the heavy left-hand, downward stroke, longer than did Rudolff.

327. *Spread of $\sqrt{}$.*—The German symbol of $\sqrt{}$ for root found its way into France in 1551 through Scheubel's publication (§ 159); it found its way into Italy in 1608 through Clavius; it found its way into England through Recorde in 1557 (§ 168) and Dee in 1570 (§ 169); it found its way into Spain in 1552 through Marco Aurel (§§ 165, 204), but in later Spanish texts of that century it was superseded by the Italian *R*. The German sign met a check in the early works of Vieta who favored Ramus' *l*, but in later editions of Vieta, brought out under the editorship of Fr. van Schooten, the sign $\sqrt{}$ displaced Vieta's earlier notations (§ 176, 177).

In Denmark Chris. Dibvadius² in 1605 gives three designations of square root, $\sqrt{}$, \sqrt{Q} , $\sqrt[3]{}$; also three designations of cube root, \sqrt{C} , \sqrt{c} , $\sqrt{c'}$; and three designations of the fourth root, $\sqrt{\sqrt{}}$, \sqrt{QQ} , $\sqrt[3]{}$.

Stifel's mode of indicating the order of roots met with greater

¹ H. Wieleitner, *Die Sieben Rechnungsarten* (Leipzig-Berlin, 1912), p. 49.

² C. Dibvadii in *Arithmetica irrationalium Euclidis* (Arnheim, 1605).

general favor than Rudolff's older and clumsier designation (§§ 153, 155).

328. *Rudolff's signs outside of Germany.*—The clumsy signs of Christoff Rudolff, in place of which Stifel had introduced in 1544 and 1553 better symbols of his own, found adoption in somewhat modified form among a few writers of later date. They occur in Aurel's *Spanish Arithmetica*, 1552 (§ 165). They are given in Recorde, *Whetstone of Wille* (1557) (§ 168), who, after introducing the first sign, $\sqrt{}$, proceeds: "The seconde signe is annexed with *Surde Cubes*, to expresse their rootes. As this $\sqrt[3]{}$.16 whiche signifieth the *Cubike roote* of .16. And $\sqrt[4]{}$.20. betokeneth the *Cubike roote* of .20. And so forthe. But many tymes it hath the *Cossike* signe with it also: as $\sqrt[3]{}$.c^e 25 the *Cubike roote* of .25. And $\sqrt[3]{}$.c^e 32. the *Cubike roote* of .32. The thirde figure doeth represente a *zenzizenzike roote*. As $\sqrt[4]{}$.12. is the *zenzizenzike roote* of .12. And $\sqrt[5]{}$.35. is the *zenzizenzike roote* of .35. And likewaies if it haue with it the *Cossike* signe .33. As $\sqrt[3]{}$ 33 24 the *zenzizenzike roote* of .24. and so of other."

The Swiss Ardüser in 1627 employed Rudolff's signs for square root and cube root.¹ J. H. Rahn in 1659 used $\sqrt[3]{}$ for evolution,² which may be a modified symbol of Rudolff; Rahn's sign is adopted by Thomas Brancker in his English translation of Rahn in 1668, also by Edward Hatton³ in 1721, and by John Kirkby⁴ in 1725. Ozanam⁵ in 1702 writes $\sqrt[3]{5} + \sqrt[4]{2}$ and also $\sqrt[3]{5} + \sqrt[4]{2}$. Samuel Jeake⁶ in 1696 gives modifications of Rudolff's signs, along with other signs, in an elaborate explanation of the "characters" of "Surdes"; $\sqrt{}$ means root, $\sqrt{}$: or V or $\sqrt{}$ universal root, $\sqrt[3]{}$ or $\sqrt[3]{}$ square root, $\sqrt[4]{}$ or $\sqrt[4]{}$ cube root, $\sqrt[5]{}$ or $\sqrt[5]{}$ squared square root, $\sqrt[6]{}$ or $\sqrt[6]{}$ sursolide root.

On the Continent, Johann Caramuel⁷ in 1670 used $\sqrt{}$ for square root and repeated the symbol $\sqrt[3]{}$ for cube root: " $\sqrt[3]{}$ 27. est Radix Cubica Numeri 27. hoc est, 3."

329. *Stevin's numeral root-indices*.—An innovation of considerable moment were Stevin's numeral indices which took the place of Stifel's letters to mark the orders of the roots. Beginning with Stifel the sign $\sqrt{}$ without any additional mark came to be interpreted as meaning specially square root. Stevin adopted this interpretation, but in the case of cube root he placed after the $\sqrt{}$ the numeral 3 inclosed in a circle (§§ 162, 163). Similarly for roots of higher order. Stevin's use of numerals met with general but not universal adoption. Among those still indicating the order of a root by the use of letters was Descartes who in 1637 indicated cube root by $\sqrt[3]{C}$. But in a letter of 1640 he¹ used the 3 and, in fact, leaned toward one of Albert Girard's notations, when he wrote $\sqrt[3]{3}.20 + \sqrt[3]{392}$ for $\sqrt[3]{20 + \sqrt[3]{392}}$. But very great diversity prevailed for a century as to the exact position of the numeral relative to the $\sqrt{}$. Stevin's $\sqrt{}$, followed by numeral indices placed within circles, was adopted by Stampioen,² and by van Schooten.³

A. Romanus displaced the circle of Stevin by two round parentheses, a procedure explained in England by Richard Sault⁴ who gives $\sqrt{(3)a+b}$ or $\sqrt{a+b}$.¹ Like Girard, Harriot writes $\sqrt[3]{3}.26 + \sqrt[3]{675}$ for $\sqrt[3]{26 + \sqrt[3]{675}}$ (see Fig. 87 in § 188). Substantially this notation was used by Descartes in a letter to Mersenne (September 30, 1640), where he represents the *racine cubique* by $\sqrt[3]{3}$, the *racine sursolide* by $\sqrt[3]{5}$, the *B sursolide* by $\sqrt[3]{7}$, and so on.⁵ Oughtred sometimes used square brackets, thus $\sqrt{[12]1000}$ for $\sqrt[12]{1000}$ (§ 183).

330. A step in the right direction is taken by John Wallis⁶ who in 1655 expresses the root indices in numerals without inclosing them in a circle as did Stevin, or in parentheses as did Romanus. However, Wallis' placing of them is still different from the modern; he writes $\sqrt[3]{R^2}$ for our $\sqrt[3]{R^2}$. The placing of the index within the opening of the radical sign had been suggested by Albert Girard as early as 1629. Wallis' notation is found in the universal arithmetic of the Spaniard, Joseph Zaragoza,⁷ who writes $\sqrt[4]{243} - \sqrt[3]{27}$ for our $\sqrt[4]{243} - \sqrt[3]{27}$, and

⁷ Joseph Zaragoza, *Arithmetica universal* (Valencia, 1669), p. 307.

$\sqrt[2]{7+\sqrt[2]{13}}$ for our $\sqrt{7+\sqrt{13}}$. Wallis employs this notation¹ again in his *Algebra* of 1685. It was he who first used general indices² in the expression $\sqrt[d]{R^d}=R$. The notation $\sqrt[4]{19}$ for $\sqrt[4]{19}$ crops out again³ in 1697 in De Lagny's $\sqrt[3]{54}-\sqrt[3]{16}=\sqrt[3]{2}$; it is employed by Thomas Walter;⁴ it is found in the *Maandelykse Mathematische Liefhebberye* (1754-69), though the modern $\sqrt[4]{}$ is more frequent; it is given in Castillion's edition⁵ of Newton's *Arithmetica universalis*.

331. The Girard plan of placing the index in the opening of the radical appears in M. Rolle's *Traité d'Algèbre* (Paris, 1690), in a letter of Leibniz⁶ to Varignon of the year 1702, in the expression $\sqrt[2]{1+\sqrt{-3}}$, and in 1708 in (a review of) G. Manfred⁷ with literal index, $\sqrt[m]{aa+bb^n}$. At this time the Leibnizian preference for $\sqrt[4]{(aa+bb)}$ in place of $\sqrt[4]{aa+bb}$ is made public;⁸ a preference which was heeded in Germany and Switzerland more than in England and France. In Sir Isaac Newton's *Arithmetica universalis*⁹ of 1707 (written by Newton sometime between 1673 and 1683, and published by Whiston without having secured the consent of Newton) the index numeral is placed after the radical, and low, as in $\sqrt[3]{3:64}$ for $\sqrt[3]{64}$, so that the danger of confusion was greater than in most other notations.

During the eighteenth century the placing of the root index in the opening of the radical sign gradually came in vogue. In 1732 one finds $\sqrt[3]{25}$ in De la Loubère;¹⁰ De Lagny¹¹ who in 1697 wrote $\sqrt[3]{}$, in 1733 wrote $\sqrt[3]{}$; Christian Wolff¹² in 1716 uses in one place the astro-

nomical character representing Aries or the ram, for the radical sign, and writes the index of the root to the right; thus \mathcal{T}^3 signifies cube root. Edward Hatton¹ in 1721 uses $\sqrt[3]{}$, $\sqrt[4]{}$, $\sqrt[5]{}$; De la Chapelle² in 1750 wrote $\sqrt[18]{b^3}$. Wolff³ in 1716 and Hindenburg⁴ in 1779 placed the index to the left of the radical sign, $\sqrt[3]{Z}$; nevertheless, the notation $\sqrt[3]{}$ came to be adopted almost universally during the eighteenth century. Variations appear here and there. According to W. J. Greenstreet,⁵ a curious use of the radical sign is to be found in Walkingame's *Tutor's Assistant* (20th ed., 1784). He employs the letter V for square root, but lets V^3 signify cube or third power, V^4 the fourth power. On the use of capital letters for mathematical signs, very often encountered in old books, as V , for $\sqrt[3]{}$, \succ for $>$, Greenstreet remarks that "authors in the eighteenth century complained of the meanness of the Cambridge University Press for using daggers set sideways instead of the usual $+$." In 1811, an anonymous arithmetician⁶ of Massachusetts suggests $\sqrt[2]{4}$, $\sqrt[3]{8}$, $\sqrt[4]{8}$ for $\sqrt[2]{4}$, $\sqrt[3]{8}$, $\sqrt[4]{8}$.

As late as 1847 one finds⁷ the notation $\sqrt[3]{b}$, $\sqrt[m]{abc}$, for the cube root and the m th root, the index appearing in front of the radical sign. This form was not adopted on account of the limitations of the printing office, for in an article in the same series, from the pen of De Morgan, the index is placed inside the opening of the radical sign.⁸ In fact, the latter notation occurs also toward the end of Parker's book (p. 131).

In a new algorithm in logarithmic theory A. Bürja⁹ proposed the sign $\sqrt[N]{a}$ to mark the n th root of the order N , of a , or the number of which the n th power of the order N is a .

332. *Rudolff and Stifel's aggregation signs*.—Their dot symbolism for the aggregation of terms following the radical sign $\sqrt{}$ was used by Peletier in 1554 (§ 172). In Denmark, Chris. Dibvadius¹ in 1605 marks aggregation by one dot or two dots, as the case may demand. Thus $\sqrt{}.5+\sqrt{}3.+\sqrt{}2$ means $\sqrt{5+\sqrt{3}+\sqrt{2}}$; $\sqrt{}.5+\sqrt{}3+\sqrt{}2$ means $\sqrt{5+\sqrt{3}+\sqrt{2}}$.

W. Snell's translation² into Latin of Ludolf van Ceulen's book on the circle contains the expression

$$\sqrt{}.2+\sqrt{}.2-\sqrt{}.2-\sqrt{}.2+\sqrt{}2\frac{1}{2}}-\sqrt{}2\frac{1}{4},$$

which is certainly neater than the modern

$$\sqrt{2+\sqrt{2-\sqrt{2-\sqrt{2+\sqrt{2\frac{1}{2}}}-\sqrt{2\frac{1}{4}}}}}.$$

The Swiss, Johann Ardüser,³ in 1627, represents $\sqrt{(2-\sqrt{3})}$ by " $\sqrt{}.2\div\sqrt{}3$ " and $\sqrt{[2+\sqrt{(2+\sqrt{2})}]}$ by " $\sqrt{}.2+\sqrt{}.2+\sqrt{}2$." This notation appears also in one of the manuscripts of René Descartes,⁴ written before the publication of his *Géométrie* in 1637.

It is well known that Oughtred in England modified the German dot symbolism by introducing the colon in its place (§ 181). He had settled upon the dot for the expression of ratic, hence was driven to alter the German notation for aggregation. Oughtred's⁵ double colons appear as in " $\sqrt{}q:aq-eg$:" for our $\sqrt{(a^2-e^2)}$.

We have noticed the use of the colon to express aggregation, in the manner of Oughtred, in the *Arithmetique made easie*, by Edmund Wingate (2d ed. by John Kersey; London, 1650), page 387; in John Wallis' *Operum mathematicorum pars altera* (Oxonii, 1656), page 186, as well as in the various parts of Wallis' *Treatise of Algebra* (London, 1685) (§ 196), and also in Jonas Moore's *Arithmetick in two Books* (London, 1660), Second Part, page 14. The 1630 edition of Wingate's book does not contain the part on algebra, nor the symbolism in question; these were probably added by John Kersey.

⁴ *Œuvres de Descartes*, Vol. X (1908) p. 248.

⁵ *Euclidis declaratio*, p. 9, in Oughtred's *Clavis* (1652).

333. *Descartes' union of radical sign and vinculum.*—René Descartes, in his *Géométrie* (1637), indicates the cube root by $\sqrt[3]{C}$. as in

$$\sqrt[3]{C \cdot \frac{1}{2}q + \sqrt{\frac{1}{4}qq - \frac{1}{27}p^3}} \text{ for our } \sqrt[3]{\frac{1}{2}q + \sqrt{\frac{1}{4}q^2 - \frac{1}{27}p^3}}.$$

Here a noteworthy innovation is the union of the radical sign $\sqrt[3]{}$ with the vinculum — (§ 191). This union was adopted in 1640 by J. J. Stampioen,¹ but only as a redundant symbol. It is found in Fr. van Schooten's 1646 edition of the collected works of Vieta (§ 177), in van Schooten's conic sections,² as also in van Schooten's Latin edition of Descartes' geometry.³ It occurs in J. H. Rahn's algebra (1659) and in Brancher's translation of 1668 (§ 194).

This combination of radical sign $\sqrt[3]{}$ and vinculum is one which has met with great favor and has maintained a conspicuous place in mathematical books down to our own time. Before 1637, this combination of radical sign and vinculum had been suggested by Descartes (*Œuvres*, Vol. X, p. 292). Descartes also leaned once toward Girard's notation.

Great as were Descartes' services toward perfecting algebraic notation, he missed a splendid opportunity of rendering a still greater service. Before him Oresme and Stevin had advanced the concept of fractional as well as of integral exponents. If Descartes, instead of extending the application of the radical sign $\sqrt[3]{}$ by adding to it the vinculum, had discarded the radical sign altogether and had introduced the notation for fractional as well as integral exponents, then it is conceivable that the further use of radical signs would have been discouraged and checked; it is conceivable that the unnecessary duplication in notation, as illustrated by $b^{\frac{1}{3}}$ and $\sqrt[3]{b^{\frac{1}{3}}}$, would have been avoided; it is conceivable that generations upon generations of pupils would have been saved the necessity of mastering the operations with two difficult notations when one alone (the exponential) would have answered all purposes. But Descartes missed this opportunity, as did later also I. Newton who introduced the notation of the fractional exponent, yet retained and used radicals.

334. *Other signs of aggregation of terms.*—Leonard and Thomas Digges,¹ in a work of 1571, state that if “the side of the Pentagon. [is] 14, the containing circles semidiameter [is]

$$\sqrt[3]{.98} + \sqrt[3]{1920\frac{1}{5}} \text{ i.e., } \sqrt{98 + \sqrt{1920\frac{1}{5}}}.$$

In the edition of 1591² the area of such a pentagon is given as

$$\sqrt[3]{.60025} + \sqrt[3]{2882400500}.$$

Vieta's peculiar notations for radicals of 1593 and 1595 are given in § 177. The *Algebra* of Herman Follinvs³ of 1622 uses parentheses in connection with the radical sign, as in $\sqrt[3]{(22 + \sqrt[3]{9})}$, our $\sqrt[3]{22 + \sqrt[3]{9}}$. Similarly, Albert Girard⁴ writes $\sqrt{(2\frac{1}{2} + \sqrt[3]{\frac{1}{4}})}$, with the simplification of omitting in case of square root the letter marking the order of the root. But, as already noted, he does not confine himself to this notation. In one place⁵ he suggests the modern designation $\sqrt[2]{}$, $\sqrt[3]{}$, $\sqrt[5]{}$.

Oughtred writes \sqrt{u} or \sqrt{b} for universal root (§ 183), but more commonly follows the colon notation (§ 181). Hérigone's notation of 1634 and 1644 is given in § 189. The Scotsman, James Gregory,⁶ writes

$$\sqrt{C(b^2c^3az^3 \dots)}, \sqrt[q]{\sqrt[q]{l^{\frac{5}{2}} + \frac{16\frac{1}{2}}{25}}}.$$

In William Molyneux⁷ one finds $\sqrt[CP^q]{P^q - Px^q}$ for $\sqrt[3]{P^q - Px^q}$. Another mode of marking the root of a binomial is seen in a paper of James Bernoulli⁸ who writes $\sqrt{}$, $ax - x^2$ for $\sqrt{ax - x^2}$. This is really the old idea of Stifel, with Hérigone's and Leibniz's comma taking the place of a dot.

The union of the radical sign and vinculum has maintained itself widely, even though it had been discouraged by Leibniz and others who aimed to simplify the printing by using, as far as possible, one-line symbols. In 1915 the Council of the London Mathematical So-

⁸ Jacob Bernoulli in *Acta eruditorum* (1697), p. 209.

ciety, in its *Suggestions for Notation and Printing*,¹ recommended that $\sqrt[4]{2}$ or $2^{\frac{1}{4}}$ be adopted in place of $\sqrt{2}$, also $\sqrt[4]{(ax^2+2bx+c)}$ or $(ax^2+2bx+c)^{\frac{1}{4}}$ in place of $\sqrt{ax^2+2bx+c}$. Bryan² would write $\sqrt{-1}$ rather than $\sqrt{-1}$.

335. *Redundancy in the use of aggregation signs*.—J. J. Stampioen marked aggregation of terms in three ways, any one of which would have been sufficient. Thus,³ he indicates $\sqrt[4]{b^3+6a^2b^2+9a^4b}$ in this manner, $\sqrt[4]{(bbb+6aa\ bb+9aaaa\ b)}$; he used here the vinculum, the round parenthesis, and the dot to designate the aggregation of the three terms. In other places, he restricts himself to the use of dots, either a dot at the beginning and a dot at the end of the expression, or a dot at the beginning and a comma at the end, or he uses a dot and parentheses.

Another curious notation, indicating fright lest the aggregation of terms be overlooked by the reader, is found in John Kersey's symbolism of 1673,⁴ $\sqrt[4]{(2):\frac{1}{2}r-\sqrt{\frac{1}{4}rr}-s}$: for $\sqrt[4]{\frac{1}{2}r-\sqrt{\frac{1}{4}r^2}-s}$. We observe here the superposition of two notations for aggregation, the Oughtredian colon placed before and after the binomial, and the vinculum. Either of these without the other would have been sufficient.

336. *Peculiar Dutch symbolism*.—A curious use of $\sqrt[4]{}$ sprang up in Holland in the latter part of the seventeenth century and maintained itself there in a group of writers until the latter part of the eighteenth century. If $\sqrt[4]{}$ is placed before a number it means "square root," if placed after it means "square." Thus, Abraham de Graaf⁵ in 1694 indicates by $\sqrt[4]{\frac{12\frac{1}{4}}{3\frac{1}{2}}}$ the square root of the fraction, by $\frac{15}{225}\sqrt[4]{}$ the square of the fraction. This notation is used often in the mathematical journal, *Maandelykse Mathematische Liefhebberij*, published at Amsterdam from 1754 to 1769. As late as 1777 it is given by L. Praalder⁶ of Utrecht, and even later (1783) by Pieter Venema.⁷ We have here the

⁵ Abraham de Graaf, *De Geheele Mathesis* (Amsterdam, 1694), p. 65, 69.

⁶ Laurens Praalder, *Mathematische Voorstellen* (Amsterdam, 1777), p. 14, 15 ff.

⁷ Pieter Venema, *Algebra ofte Stel-Konst*, Vyfde Druk (Amsterdam, 1783), p. 168, 173.

same general idea that was introduced into other symbolisms, according to which the significance of the symbol depends upon its relative position to the number or algebraic expression affected. Thus with Pacioli $R200$ meant $\sqrt{200}$, but $R3^a$ meant the second power (§§ 135, 136). With Stevin (§ 162, 163), $\textcircled{3}20$ meant 20^3 , but $20\textcircled{3}$ meant $20x^3$. With L. Schoner $5l$ meant $5x$, but $l5$ meant $\sqrt{5}$ (§ 291). We may add that in the 1730 edition of Venema's algebra brought out in New York City radical expressions do not occur, as I am informed by Professor L. G. Simons, but a letter placed on the left of an equation means division of the members of the equation by it; when placed on the right, multiplication is meant. Thus (p. 100):

$$\text{“ } b \left| \begin{array}{l} bx = 2a \\ x = \frac{2a}{b} \end{array} \right. \text{”}$$

and (p. 112):

$$\text{“ } 5 - \frac{4500}{x} = 1\frac{1}{2} - \frac{1000}{x} \text{”}$$

$$\frac{5x - 4500}{5x - 4500} = \frac{1\frac{1}{2}x - 1000}{1\frac{1}{2}x - 1000} \quad x.$$

Similar is Prändel's use of $\sqrt{}$ as a marginal symbol, indicating that the square root of both sides of an equation is to be taken. His marginal symbols are shown in the following:¹

$$\begin{array}{rcl} \text{“ } & \frac{V^2}{a} = \frac{1}{4}(a-p) \\ \times a & V^2 = \frac{1}{4}(a^2 - ap) = \frac{1}{4}a(a-p) . \\ \sqrt{} & V = \frac{1}{2}\sqrt{a(a-p)} . \text{”} \end{array}$$

337. *Principal root-values*.—For the purpose of distinguishing between the principal value of a radical expression and the other values, G. Peano² indicated by $\sqrt[m]{*a}$ all the m values of the radical, reserving $\sqrt[m]{a}$ for the designation of its “principal value.” This notation is adopted by O. Stolz and J. A. Gmeiner³ in their *Theoretische Arithmetik* (see also § 312).

338. *Recommendation of United States National Committee.*—"With respect to the root sign, $\sqrt{}$, the committee recognizes that convenience of writing assures its continued use in many cases instead of the fractional exponent. It is recommended, however, that in algebraic work involving complicated cases the fractional exponent be preferred. Attention is called to the fact that the symbol $\sqrt[n]{a}$ (a representing a positive number) means only the positive square root and that the symbol $\sqrt[n]{a}$ means only the principal n th root, and similarly for $a^{\frac{1}{n}}$, $a^{\frac{1}{n}}$."¹

SIGNS FOR UNKNOWN NUMBERS

339. *Early forms.*—Much has already been said on symbolisms used to represent numbers that are initially unknown in a problem, and which the algebraist endeavors to ascertain. In the Ahmes papyrus there are signs to indicate "heap" (§ 23); in Diophantus a Greek letter with an accent appears (§ 101); the Chinese had a positional mode of indicating one or more unknowns; in the Hindu Bakhshālī manuscript the use of a dot is invoked (§ 109). Brahmagupta and Bhāskara did not confine the symbolism for the unknown to a single sign, but used the names of colors to designate different unknowns (§§ 106, 108, 112, 114). The Arab Abu Kamil² (about 900 A.D.), modifying the Hindu practice of using the names of colors, designated the unknowns by different coins, while later al-Karkhī (following perhaps Greek sources)³ called one unknown "thing," a second "measure" or "part," but had no contracted sign for them. Later still al-Qalasādi used a sign for unknown (§ 124). An early European sign is found in Regiomontanus (§ 126), later European signs occur in Pacioli (§§ 134, 136), in Christoff Rudolff (§§ 148, 149, 151),⁴ in Michael Stifel who used more than one notation (§§ 151, 152), in Simon Stevin (§ 162), in L. Schoner (§ 322), in F. Vieta (§§ 176–78), and in other writers (§§ 117, 138, 140, 148, 164, 173, 175, 176, 190, 198).

Luca Pacioli remarks⁵ that the older textbooks usually speak of

¹ *Report of the National Committee on Mathematical Requirements under the Auspices of the Mathematical Association of America* (1923), p. 81.

the first and the second *cosa* for the unknowns, that the newer writers prefer *cosa* for the unknown, and *quantita* for the others. Pacioli abbreviates those *co.* and *q^a*.

Vieta's convention of letting vowels stand for unknowns and consonants for knowns (§§ 164, 176) was favored by Albert Girard, and also by W. Oughtred in parts of his *Algebra*, but not throughout. Near the beginning Oughtred used *Q* for the unknown (§ 182).

The use of *N* (*numerus*) for *x* in the treatment of numerical equations, and of *Q*, *C*, etc., for the second and third powers of *x*, is found in Xylander's edition of Diophantus of 1575 (§ 101), in Vieta's *De emendatione aequationum* of 1615 (§ 178), in Bachet's edition of Diophantus of 1621, in Camillo Glorioso in 1627 (§ 196). In numerical equations Oughtred uses *l* for *x*, but the small letters *q*, *c*, *qq*, *qc*, etc., for the higher powers of *x* (§ 181). Sometimes Oughtred employs also the corresponding capital letters. Descartes very often used, in his correspondence, notations different from his own, as perhaps more familiar to his correspondents than his own. Thus, as late as 1640, in a letter to Mersenne (September 30, 1640), Descartes¹ writes "*1C - 6N = 40*," which means $x^3 - 6x = 40$. In the *Regulae ad directionem ingenii*, Descartes represents² by *a*, *b*, *c*, etc., known magnitudes and by *A*, *B*, *C*, etc., the unknowns; this is the exact opposite of the use of these letters found later in Rahn.

Crossed numerals representing powers of unknowns.—Interesting is the attitude of P. A. Cataldi of Bologna, who deplored the existence of many different notations in different countries for the unknown numbers and their powers, and the inconveniences resulting from such diversity. He points out also the difficulty of finding in the ordinary printing establishment the proper type for the representation of the different powers. He proposes³ to remove both inconveniences by the use of numerals indicating the powers of the unknown and distinguishing them from ordinary numbers by crossing them out, so that \emptyset , \ast , \mathcal{Z} , \mathcal{Z} , . . . , would stand for x^0 , x' , x^2 , x^3 Such crossed numerals, he argued, were convenient and would be found in printing offices since they are used in arithmetics giving the scratch method of dividing, called by the Italians the "a Galea" method. The reader will recall that Cataldi's notation closely resembles that of Leonard

¹ *Œuvres de Descartes*, Vol. III (1899), p. 190, 196, 197; also Vol. XII, p. 279.

² *Op. cit.*, Vol. X (1908), p. 455, 462.

³ P. A. Cataldi, *Trattato dell'algebra proportionale* (Bologna, 1610), and in his later works. See G. Wertheim in *Bibliotheca mathematica* (3d ser.), Vol. II (1901), p. 146, 147.

and Thomas Digges in England (§ 170). These symbols failed of adoption by other mathematicians. We have seen that in 1627 Camillo Glorioso, in a work published at Naples,¹ wrote N for x , and $q, c, qq, qc, cc, qqc, qcc$, and ccc for x^2, x^3, \dots, x^9 , respectively (§ 196). In 1613 Glorioso had followed Stevin in representing an unknown quantity by $1\odot$.

340. *Descartes' z, y, x*.—The use of $z, y, x \dots$ to represent unknowns is due to René Descartes, in his *La géométrie* (1637). Without comment, he introduces the use of the first letters of the alphabet to signify *known* quantities and the use of the last letters to signify *unknown* quantities. His own language is: "... l'autre, LN , est $\frac{1}{2}a$ la moitié de l'autre quantité connue, qui estoit multipliée par z , que ie suppose estre la ligne inconnue."² Again: "... ie considere ... Que le segment de la ligne AB , qui est entre les points A et B , soit nommé x , et que BC soit nommé y ; ... la proportion qui est entre les costés AB et BR est aussy donnée, et ie la pose comme de z a b ; de façon qu' AB estant x , RB sera $\frac{bx}{z}$, et la toute CR sera $y + \frac{bx}{z}$" Later he says: "et pour ce que CB et BA sont deux quantités indeterminées et inconnuës, ie les nomme, l'une y ; et l'autre x . Mais, affin de trouver le rapport de l'une a l'autre, ie considere aussy les quantités connuës qui determinent la description de cete ligne courbe: comme GA que je nomme a , KL que je nomme b , et NL , parallele a GA , que ie nomme C ."³ As co-ordinates he uses later only x and y . In equations, in the third book of the *Géométrie*, x predominates. In manuscripts written in the interval 1629–40, the unknown z occurs only once.⁴ In the other places x and y occur. In a paper on Cartesian ovals,⁵ prepared before 1629, x alone occurs as unknown, y being used as a parameter. This is the earliest place in which Descartes used one of the last letters of the alphabet to represent an unknown. A little later he used x, y, z again as known quantities.⁶

Some historical writers have focused their attention upon the x , disregarding the y and z , and the other changes in notation made by

¹ Camillo Gloriosi, *Exercitationes mathematicales, decas I* (Naples, 1627). Also *Ad theorema geometricum, á nobilissimo viro propositum, Joannis Camilli Gloriosi* (Venice, 1613), p. 26. It is of interest that Gloriosi succeeded Galileo in the mathematical chair at Padua.

⁵ *Ibid.*, p. 310.

⁶ *Ibid.*, p. 299.

Descartes; these writers have endeavored to connect this x with older symbols or with Arabic words. Thus, J. Tropske,¹ P. Treutlein,² and M. Curtze³ advanced the view that the symbol for the unknown used by early German writers, \mathcal{X} , looked so much like an x that it could easily have been taken as such, and that Descartes actually did interpret and use it as an x . But Descartes' mode of introducing the knowns a, b, c , etc., and the unknowns z, y, x makes this hypothesis improbable. Moreover, G. Eneström has shown⁴ that in a letter of March 26, 1619, addressed to Isaac Beeckman, Descartes used the symbol \mathcal{X} as a symbol in form distinct from x , hence later could not have mistaken it for an \mathcal{X} . At one time, before 1637, Descartes⁵ used x along the side of \mathcal{X} ; at that time x, y, z are still used by him as symbols for known quantities. German symbols, including the \mathcal{X} for x , as they are found in the algebra of Clavius, occur regularly in a manuscript⁶ due to Descartes, the *Opusculæ de 1619-1621*.

All these facts caused Tropske in 1921 to abandon his old view⁷ on the origin of x , but he now argues with force that the resemblance of x and \mathcal{X} , and Descartes' familiarity with \mathcal{X} , may account for the fact that in the latter part of Descartes' *Géométrie* the x occurs more frequently than z and y . Eneström, on the other hand, inclines to the view that the predominance of x over y and z is due to typographical reasons, type for x being more plentiful because of the more frequent occurrence of the letter x , to y and z , in the French and Latin languages.⁸

There is nothing to support the hypothesis on the origin of x due to Wertheim,⁹ namely, that the Cartesian x is simply the notation of the Italian Cataldi who represented the first power of the unknown by a crossed "one," thus I . Nor is there historical evidence

to support the statement found in Noah Webster's *Dictionary*, under the letter *x*, to the effect that "*x* was used as an abbreviation of *Ar. shei* a thing, something, which, in the Middle Ages, was used to designate the unknown, and was then prevailingly transcribed as *xei*."

341. *Spread of Descartes' signs*.—Descartes' *x*, *y*, and *z* notation did not meet with immediate adoption. J. H. Rahn, for example, says in his *Teutsche Algebra* (1659): "Descartes' way is to signify *known* quantities by the *former* letters of the alphabet, and *unknown* by the *latter* [*z*, *y*, *x*, etc.]. But I choose to signify the *unknown* quantities by *small* letters and the *known* by *capitals*." Accordingly, in a number of his *geometrical* problems, Rahn uses *a* and *A*, etc., but in the book as a whole he uses *z*, *y*, *x* freely.

As late as 1670 the learned bishop, Johann Caramuel, in his *Mathesis biceps* ... , Campagna (near Naples), page 123, gives an old notation. He states an old problem and gives the solution of it as found in Geysius; it illustrates the rhetorical exposition found in some books as late as the time of Wallis, Newton, and Leibniz. We quote: "Dicebat Augias Herculi: Meorum armentorum media pars est in tali loco octavi in tali, decima in tali, 20^{ma} in tali 60^{ma} in tali, & 50 . sunc hic. Et Geysius libr. 3 *Cossa* Cap. 4. haec pecora numeraturus sic scribit.

"Finge 1. *a*. partes $\frac{1}{2}a$, $\frac{1}{3}a$, $\frac{1}{10}a$, $\frac{1}{20}a$, $\frac{1}{60}a$ & additae (hoc est, in summam reductae) sunt $\frac{1}{2}a$ a quibus de 1. *a*. sublatis, restant $\frac{1}{2}a$ a aequalia 50. Jam, quia sictus, est fractio, multiplicando reducatur, & 1. *a*. aequantur 240. Hic est numerus pecorum Augiae." ("Augias said to Hercules: 'Half of my cattle is in such a place, $\frac{1}{3}$ in such, $\frac{1}{10}$ in such, $\frac{1}{20}$ in such, $\frac{1}{60}$ in such, and here there are 50. And Geysius in Book 3, *Cossa*, Chap. 4, finds the number of the herd thus: Assume 1. *a*., the parts are $\frac{1}{2}a$, $\frac{1}{3}a$, $\frac{1}{10}a$, $\frac{1}{20}a$, $\frac{1}{60}a$, and these added [i.e., reduced to a sum] are $\frac{1}{2}a$ which subtracted from 1. *a*., leaves $\frac{1}{2}a$, equal to 50. Now, the fraction is removed by multiplication, and 1. *a* equal 240. This is the number of Augias' herd.'")

Descartes' notation, *x*, *y*, *z*, is adopted by Gerard Kinckhuysen,¹ in his *Algebra* (1661). The earliest systematic use of three co-ordinates in analytical geometry is found in De la Hire, who in his *Nouveaux élémens des sections coniques* (Paris, 1679) employed (p. 27) *x*, *y*, *v*. A. Parent² used *x*, *y*, *z*; Euler³, in 1728, *t*, *x*, *y*; Joh. Bernoulli,⁴ in 1715,

x, y, z in a letter (February 6, 1715) to Leibniz. H. Pitot¹ applied the three co-ordinates to the helix in 1724.

SIGNS OF AGGREGATION

342. *Introduction.*—In a rhetorical or syncopated algebra, the aggregation of terms could be indicated in words. Hence the need for symbols of aggregation was not urgent. Not until the fifteenth and sixteenth centuries did the convenience and need for such signs definitely present itself. Various devices were invoked: (1) the horizontal bar, placed below or above the expression affected; (2) the use of abbreviations of words signifying aggregation, as for instance u or v for *universalis* or *vniversalis*, which, however, did not always indicate clearly the exact range of terms affected; (3) the use of dots or commas placed before the expression affected, or at the close of such an expression, or (still more commonly) placed both before and after; (4) the use of parentheses (round parentheses or brackets or braces). Of these devices the parentheses were the slowest to find wide adoption in all countries, but now they have fairly won their place in competition with the horizontal bar or vinculum. Parentheses prevailed for typographical reasons. Other things being equal, there is a preference for symbols which proceed in orderly fashion as do the letters in ordinary printing, without the placing of signs in high or low positions that would break a line into two or more sublines. A vinculum at once necessitates two terraces of type, the setting of which calls for more time and greater technical skill. At the present time

¹ H. Pitot, *Mémoires de l'académie d. scien.*, année 1724 (Paris, 1726). Taken from H. Wieleitner, *Geschichte der Mathematik*, 2. Teil, 2. Hälfte (Berlin und Leipzig, 1921), p. 92.

To what extent the letter x has been incorporated in mathematical language is illustrated by the French expression *être fort en x*, which means "being strong in mathematics." In the same way, *tête à x* means "a mathematical head." The French give an amusing "demonstration" that old men who were *tête à x* never were pressed into military service so as to have been conscripts. For, if they were conscripts, they would now be *ex*-conscripts. Expressed in symbols we would have

$$\theta x = \text{ex-conscript.}$$

Dividing both sides by x gives

$$\theta = \text{e-conscript.}$$

Dividing now by e yields

$$\text{conscript} = \frac{\theta}{e}.$$

According to this, the conscript would be *la tête assurée* (i.e., θ over e , or, the head assured against casualty), which is absurd.

the introducing of typesetting machines and the great cost of typesetting by hand operate against a double or multiple line notation. The dots have not generally prevailed in the marking of aggregation for the reason, no doubt, that there was danger of confusion since dots are used in many other symbolisms—those for multiplication, division, ratio, decimal fractions, time-derivatives, marking a number into periods of two or three digits, etc.

343. *Aggregation expressed by letters.*—The expression of aggregation by the use of letters serving as abbreviations of words expressing aggregation is not quite as old as the use of horizontal bars, but it is more common in works of the sixteenth century. The need of marking the aggregation of terms arose most frequently in the treatment of radicals. Thus Pacioli, in his *Summa* of 1494 and 1523, employs *v* (*vniversale*) in marking the root of a binomial or polynomial (§ 135). This and two additional abbreviations occur in Cardan (§ 141). The German manuscript of Andreas Alexander (1524) contains the letters *cs* for *communis* (§ 325); Chr. Rudolff sometimes used the word “collect,” as in “ $\sqrt{\text{des collects } 17 + \sqrt{208}}$ ” to designate $\sqrt{17 + \sqrt{208}}$.¹ J. Scheubel adopted *Ra. col.* (§ 159). S. Stevin, Fr. Vieta, and A. Romanus wrote *bin.*, or *bino.*, or *binomia*, *trinom.*, or similar abbreviations (§ 320). The *u* or *v* is found again in Pedro Nuñez (who uses also *L* for “ligature”),² Leonard and Thomas Digges (§ 334), in J. R. Brasser³ who in 1663 lets *v* signify “universal radix” and writes “ $v\sqrt{.8 \div \sqrt{45}}$ ” to represent $\sqrt{8 - \sqrt{45}}$. W. Oughtred sometimes wrote \sqrt{u} or \sqrt{b} (§§ 183, 334). In 1685 John Wallis⁴ explains the notations $\sqrt{b:2 + \sqrt{3}}$, $\sqrt{r:2 - \sqrt{3}}$, $\sqrt{u:2 \pm \sqrt{3}}$, $\sqrt{2 \pm \sqrt{3}}$, $\sqrt{:2 \pm \sqrt{3}}$, where *b* means “binomial,” *u* “universal,” *r* “residual,” and sometimes uses redundant forms like $\sqrt{b:\sqrt{5} + 1}:$.

344. *Aggregation expressed by horizontal bars or vinculum.*—The use of the horizontal bar to express the aggregation of terms goes back to the time of Nicolas Chuquet who in his manuscript (1484) underlines the parts affected (§ 130). We have seen that the same idea is followed by the German Andreas Alexander (§ 325) in a manuscript of 1545, and by the Italian Raffaele Bombelli in the manuscript edition

⁴ John Wallis, *Treatise of Algebra* (London, 1685), p. 109, 110. The use of letters for aggregation practically disappeared in the seventeenth century.

of his algebra (about 1550) where he wrote $\sqrt[3]{2+\sqrt{-121}}$ in this manner:¹ $R^3[2.p.R[0 \text{ m } 121]]$; parentheses were used and, in addition, vinculums were drawn underneath to indicate the range of the parentheses. The employment of a long horizontal brace in connection with the radical sign was introduced by Thomas Harriot² in 1631; he expresses aggregation thus: $\sqrt{ccc+\sqrt{ccccc-bbbbbb}}$. This notation may, perhaps, have suggested to Descartes his new radical symbolism of 1637. Before that date, Descartes had used dots in the manner of Stifel and Van Ceulen. He wrote³ $\sqrt{\cdot 2}-\sqrt{\cdot 2}$ for $\sqrt{2}-\sqrt{2}$. He attaches the vinculum to the radical sign $\sqrt{}$ and writes $\sqrt{a^2+b^2}$, $\sqrt{-\frac{1}{2}a+\sqrt{\frac{1}{2}aa+bb}}$, and in case of cube roots $\sqrt[3]{C.\frac{1}{2}q+\sqrt{\frac{1}{4}gg-27p^3}}$. Descartes does not use parentheses in his *Géométrie*. Descartes uses the horizontal bar only in connection with the radical sign. Its general use for aggregation is due to Fr. van Schooten, who, in editing Vieta's collected works in 1646, discarded parentheses and placed a horizontal bar above the parts affected. Thus Van Schooten's " B in D quad. + B in D " means $B(D^2+BD)$. Vieta⁴ himself in 1593 had written this expression differently, namely, in this manner:

$$B \text{ in } \left\{ \begin{array}{l} D. \text{ quadratum} \\ + B \text{ in } D \end{array} \right.$$

B. Cavalieri in his *Geometria indivisibilibae* and in his *Exercitationes geometriae sex* (1647) uses the vinculum in this manner, \overline{AB} , to indicate that the two letters A and B are not to be taken separately, but conjointly, so as to represent a straight line, drawn from the point A to the point B .

Descartes' and Van Schooten's stressing the use of the vinculum led to its adoption by J. Prestet in his popular text, *Elemens des Mathématiques* (Paris, 1675). In an account of Rolle⁵ the cube root is to be taken of $2+\overline{R.-121}$, i.e., of $2+\sqrt{-121}$. G. W. Leibniz⁶ in a

⁶ G. W. Leibniz' letter to D. Oldenburgh, Feb. 3, 1672-73, printed in J. Collin's *Commercium epistolicum* (1712).

letter of 1672 uses expressions like $\overline{a \oslash b \oslash b \oslash c \oslash b \oslash c \oslash c \oslash d}$, where \oslash signifies "difference." Occasionally he uses the vinculum until about 1708, though usually he prefers round parentheses. In 1708 Leibniz' preference for round parentheses (§ 197) is indicated by a writer in the *Acta eruditorum*. Joh. (1) Bernoulli, in his *Lectiones de calculo differentialium*, uses vinculum but no parentheses.¹

345. In England the notations of W. Oughtred, Thomas Harriot, John Wallis, and Isaac Barrow tended to retard the immediate introduction of the vinculum. But it was used freely by John Kersey (1673)² who wrote $\sqrt{(2): \frac{1}{2}r - \sqrt{\frac{1}{4}rr - s}}$: and by Newton, as, for instance, in his letter to D. Oldenburgh of June 13, 1676, where he gives

the binomial formula as the expansion of $\overline{P+PQ}^{\frac{m}{n}}$. In his *De Analysi per Aequationes numero terminorum Infinitas*, Newton writes³

$y - 4 \times y + 5 \times y - 12 \times y + 17 = 0$ to represent $\{(y-4)y-5\}y-12\}y+17=0$. This notation was adopted by Edmund Halley,⁴ David Gregory, and John Craig; it had a firm foothold in England at the close of the seventeenth century. During the eighteenth century it was the regular symbol of aggregation in England and France; it took the place very largely of the parentheses which are in vogue in our day. The vinculum appears to the exclusion of parentheses in the *Geometria organica* (1720) of Colin Maclaurin, in the *Elements of Algebra* of Nicholas Saunderson (Vol. I, 1741), in the *Treatise of Algebra* (2d ed.; London, 1756) of Maclaurin. Likewise, in Thomas Simpson's *Mathematical Dissertations* (1743) and in the 1769 London edition of Isaac Newton's *Universal Arithmetick* (translated by Ralphson and revised by Cunn), vinculum is used and parentheses do not occur. Some use of the vinculum was made nearly everywhere during the eighteenth century, especially in connection with the radical sign $\sqrt{\quad}$, so as to produce $\sqrt{\quad}$. This last form has maintained its place down to the present time. However, there are eighteenth-century writers who avoid the vinculum altogether even in connection with the radical sign, and use

parentheses exclusively. Among these are Poleni (1729),¹ Cramer (1750),² and Cossali (1797).³

346. There was considerable vacillation on the use of the vinculum in designating the square root of minus unity. Some authors wrote $\sqrt{-1}$; others wrote $\sqrt{-1}$ or $\sqrt{(-1)}$. For example, $\sqrt{-1}$ was the designation adopted by J. Wallis,⁴ J. d'Alembert,⁵ I. A. Segner,⁶ C. A. Vandermonde,⁷ A. Fontaine.⁸ Odd in appearance is an expression of Euler,⁹ $\sqrt{(2\sqrt{-1}-4)}$. But $\sqrt{(-1)}$ was preferred by Du Séjour¹⁰ in 1768 and by Waring¹¹ in 1782; $\sqrt{-1}$ by Laplace¹² in 1810.

347. It is not surprising that, in times when a notation was passing out and another one taking its place, cases should arise where both are used, causing redundancy. For example, J. Stampioen in Holland sometimes expresses aggregation of a set of terms by three notations, any one of which would have been sufficient; he writes¹³ in 1640, $\sqrt{\cdot(aaa+6aab+9bba)}$, where the dot, the parentheses, and the vinculum appear; John Craig¹⁴ writes $\sqrt{2ay-y^2}$: and $\sqrt{\cdot\sqrt{6a^4-\frac{3}{2}a^2}}$, where the colon is the old Oughtredian sign of aggregation, which is here superfluous, because of the vinculum. Tautology in notation is found in Edward Cocker¹⁵ in expressions like $\sqrt{aa+bb}$, $\sqrt{c+\frac{1}{4}bb-\frac{1}{2}b}$, and

a few times in John Wallis.¹ In the *Acta eruditorum* (1709), page 327, one finds $ny\sqrt{a} = \frac{2}{3}\sqrt{[(x-nna)^3]}$, where the [] makes, we believe, its first appearance in this journal, but does so as a redundant symbol.

348. *Aggregation expressed by dots*.—The denoting of aggregation by placing a dot before the expression affected is first encountered in Christoff Rudolff (§ 148). It is found next in the *Arithmetica integra* of M. Stifel, who sometimes places a dot also at the end. He writes²

$\sqrt{z}.12 + \sqrt{z} 6 + .\sqrt{z}.12 - \sqrt{z} 6$ for our $\sqrt{12 + \sqrt{6}} + \sqrt{12 - \sqrt{6}}$; also $\sqrt{z}.144 - 6 + \sqrt{z}.144 - 6$ for $\sqrt{144 - 6} + \sqrt{144 - 6}$. In 1605 C. Dibadius³ writes $\sqrt{.2} - \sqrt{.2} + \sqrt{.2} + \sqrt{.2} + \sqrt{.2} + \sqrt{.2}$ as the side of a regular polygon of 128 sides inscribed in a circle of unit radius, i.e.,

$\sqrt{2 - \sqrt{2 + \sqrt{2 + \sqrt{2 + \sqrt{2 + \sqrt{2}}}}}}$ (see also § 332). It must be admitted that this old notation is simpler than the modern. In Snell's translation⁴ into Latin (1610) of Ludolph van Ceulen's work on the circle is given the same notation, $\sqrt{.2} + \sqrt{.2} - \sqrt{.2} - \sqrt{.2} + \sqrt{2\frac{1}{2}} - \sqrt{2\frac{1}{4}}$. In Snell's 1615 translation⁵ into Latin of Ludolph's arithmetic and geometry is given the number $\sqrt{.2} - \sqrt{.2\frac{1}{2}} + \sqrt{1\frac{1}{4}}$ which, when divided by $\sqrt{.2} + \sqrt{.2\frac{1}{2}} + \sqrt{1\frac{1}{4}}$, gives the quotient $\sqrt{5+1} - \sqrt{.5} + \sqrt{20}$. The Swiss Joh. Ardüser⁶ in 1646 writes $\sqrt{.2} \div \sqrt{.2} + \sqrt{.2} + \sqrt{.2} + \sqrt{2} + \sqrt{.2} + \sqrt{.2} + \sqrt{.2} + \sqrt{3}$, etc., as the side of an inscribed polygon of 768 sides, where \div means "minus."

The substitution of two dots (the colon) in the place of the single dot was effected by Oughtred in the 1631 and later editions of his *Clavis mathematicae*. With him this change became necessary when he adopted the single dot as the sign of ratio. He wrote ordinarily $\sqrt{q:BC_q - BA_q}$: for $\sqrt{BC^2 - BA^2}$, placing colons before and after the terms to be aggregated (§ 181).⁷

⁷ W. Oughtred, *Clavis mathematicæ* (1652), p. 104.

Sometimes, when all the terms to the end of an expression are to be aggregated, the closing colon is omitted. In rare instances the opening colon is missing. A few times in the 1694 English edition, dots take the place of the colon. Oughtred's colons were widely used in England. As late as 1670 and 1693 John Wallis¹ writes $\sqrt{5-2\sqrt{3}}$. It occurs in Edward Cocker's² arithmetic of 1684, Jonas Moore's arithmetic³ of 1688, where $C:A+E$ means the cube of $(A+E)$. James Bernoulli⁴ gives in 1689 $\sqrt{a}+\sqrt{a}+\sqrt{a}+\sqrt{a}+\sqrt{a}+$, etc. These methods of denoting aggregation practically disappeared at the beginning of the eighteenth century, but in more recent time they have been reintroduced. Thus, R. Carmichael⁵ writes in his *Calculus of Operations*: " $D. uv=u. Dv+Du. v.$ " G. Peano has made the proposal to employ points as well as parentheses.⁶ He lets $a.bc$ be identical with $a(bc)$, $a:bc.d$ with $a[(bc)d]$, $ab.cd:e.fg \therefore hk.l$ with $\{[(ab)(cd)][e(fg)]\} [(hk)l]$.

349. *Aggregation expressed by commas*.—An attempt on the part of Hérigone (§ 189) and Leibniz to give the comma the force of a symbol of aggregation, somewhat similar to Rudolff's, Stifel's, and van Ceulen's previous use of the dot and Oughtred's use of the colon, was not successful. In 1702 Leibniz⁷ writes $c-b, l$ for $(c-b)l$, and $c-b, d-b, l$ for $(c-b)(d-b)l$. In 1709 a reviewer⁸ in the *Acta eruditorum* represents $(m \div [m-1])x^{(m-1) \div m}$ by $(m, : m-1)x^{m-1, : m}$, a designation somewhat simpler than our modern form.

350. *Aggregation expressed by parenthesis* is found in rare instances as early as the sixteenth century. Parentheses present comparatively no special difficulties to the typesetter. Nevertheless, it took over two centuries before they met with general adoption as mathematical symbols. Perhaps the fact that they were used quite extensively as purely rhetorical symbols in ordinary writing helped to

retard their general adoption as mathematical symbols. John Wallis, for example, used parentheses very extensively as symbols containing parenthetical rhetorical statements, but made practically no use of them as symbols in algebra.

As a rhetorical sign to inclose an auxiliary or parenthetical statement parentheses are found in Newton's *De analysi per equationes numero terminorum infinitas*, as given by John Collins in the *Commercium epistolicum* (1712). In 1740 De Gua¹ wrote equations in the running text and inclosed them in parentheses; he wrote, for example, "... seroit $(7a-3x \cdot dx = 3\sqrt{2ax-xx} \cdot dx)$ et où l'arc de cercle. ..."

English mathematicians adhered to the use of vinculum, and of colons placed before and after a polynomial, more tenaciously than did the French; while even the French were more disposed to stress their use than were Leibniz and Euler. It was Leibniz, the younger Bernoullis, and Euler who formed the habit of employing parentheses more freely and to resort to the vinculum less freely than did other mathematicians of their day. The straight line, as a sign of aggregation, is older than the parenthesis. We have seen that Chuquet, in his *Triparty* of 1484, underlined the terms that were to be taken together.

351. *Early occurrence of parentheses*.—Brackets² are found in the manuscript edition of R. Bombelli's *Algebra* (about 1550) in the expressions like $R^2[2\sqrt{R}[0\sqrt{121}]]$ which stands for $\sqrt[3]{2-\sqrt{-121}}$.

In the printed edition of 1572 an inverted capital letter *L* was employed to express *radix legata*; see the facsimile reproduction (Fig. 50). Michael Stifel does not use parentheses as signs of aggregation in his printed works, but in one of his handwritten marginal notes³ occurs the following: "... *faciant aggregatum* $(12-\sqrt{44})$ *quod sumptum cum* $(\sqrt{44}-2)$ *faciat* 10" (i.e., "... One obtains the aggregate $(12-\sqrt{44})$, which added to $(\sqrt{44}-2)$ makes 10"). It is our opinion that these parentheses are punctuation marks, rather than mathematical symbols; signs of aggregation are not needed here. In the 1593 edition of F. Vieta's *Zetetica*, published in Turin, occur braces and brackets (§ 177) sometimes as open parentheses, at other times as closed ones. In Vieta's collected works, edited by Fr. van Schooten

¹ Jean Paul de Gua de Malves, *Usages de l'analyse de Descartes* (Paris, 1740), p. 302.

in 1646, practically all parentheses are displaced by vinculum. However, in J. L. de Vaulezard's translation¹ into French of Vieta's *Zetetica* round parentheses are employed. Round parentheses are encountered in Tartaglia,² Cardan (but only once in his *Ars Magna*),³ Clavius (see Fig. 66), Errard de Bar-le-Duc,⁴ Follinus,⁵ Girard,⁶ Norwood,⁷ Hume,⁸ Stampioen, Henrion, Jacobo de Billy,⁹ Renaldini¹⁰ and Foster.¹¹ This is a fairly representative group of writers using parentheses, in a limited degree; there are in this group Italians, Germans, Dutch, French, English. And yet the mathematicians of none of the countries represented in this group adopted the general use of parentheses at that time. One reason for this failure lies in the fact that the vinculum, and some of the other devices for expressing aggregation, served their purpose very well. In those days when machine processes in printing were not in vogue, and when typesetting was done by hand, it was less essential than it is now that symbols should, in orderly fashion, follow each other in a line. If one or more vinculum were to be placed above a given polynomial, such a demand upon the printer was less serious in those days than it is at the present time.

And so it happened that in the second half of the seventeenth century, parentheses occur in algebra less frequently than during the first half of that century. However, voices in their favor are heard. The Dutch writer, J. J. Blassière,¹ explained in 1770 the three notations $(2a+5b)(3a-4b)$, $(2a+5b) \times (3a-4b)$, and $\overline{2a+5b} \times 3a-4b$, and remarked: "Mais comme la première manière de les enfermer entre des Parenthèses, est la moins sujette à erreur, nous nous en servirons dans la suite." E. Waring in 1762² uses the vinculum but no parentheses; in 1782³ he employs parentheses and vinculum interchangeably. Before the eighteenth century parentheses hardly ever occur in the *Philosophical Transactions* of London, in the publications of the Paris Academy of Sciences, in the *Acta eruditorum* published in Leipzig. But with the beginning of the eighteenth century, parentheses do appear. In the *Acta eruditorum*, Carré⁴ of Paris uses them in 1701, G. W. Leibniz⁵ in 1702, a reviewer of Gabriele Manfredi⁶ in 1708. Then comes in 1708 (§ 197) the statement of policy⁷ in the *Acta eruditorum* in favor of the Leibnizian symbols, so that "in place of $\sqrt{aa+bb}$ we write $\sqrt{(aa+bb)}$ and for $\overline{aa+bb} \times c$ we write $aa+bb, c$. . . we shall designate $\overline{aa+bb}^m$ by $(aa+bb)^m$: whence $\sqrt[m]{aa+bb}$ will be $= (aa+bb)^{1:m}$ and $\sqrt[m]{\overline{aa+bb}^n} = (aa+bb)^{n:m}$. Indeed, we do not doubt that all mathematicians reading these *Acta* recognize the pre-eminence of Mr. Leibniz' symbolism and agree with us in regard to it."

From now on round parentheses appear frequently in the *Acta eruditorum*. In 1709 square brackets make their appearance.⁸ In the *Philosophical Transactions* of London⁹ one of the first appearances of parentheses was in an article by the Frenchman P. L. Maupertuis in 1731, while in the *Histoire de l'académie royale des sciences* in Paris,¹⁰

¹⁰ Johann II Bernoulli, *Histoire de l'académie royale des sciences*, année 1732 (Paris, 1735), p. 240 ff.

Johann (John) Bernoulli of Bale first used parentheses and brackets in the volume for the year 1732. In the volumes of the Petrograd Academy, J. Hermann¹ uses parentheses, in the first volume, for the year 1726; in the third volume, for the year 1728, L. Euler² and Daniel Bernoulli used round parentheses and brackets.

352. The constant use of parentheses in the stream of articles from the pen of Euler that appeared during the eighteenth century contributed vastly toward accustoming mathematicians to their use. Some of his articles present an odd appearance from the fact that the closing part of a round parenthesis is much larger than the opening part,³ as in $(1 - \frac{z}{\pi})(1 - \frac{z}{\pi - s})$. Daniel Bernoulli⁴ in 1753 uses round

parentheses and brackets in the same expression while T. U. T. Aepinus⁵ and later Euler use two types of round parentheses of this sort, $C(\beta + \gamma)(M - 1) + AM\bigcirc$. In the publications of the Paris Academy, parentheses are used by Johann Bernoulli (both round and square ones),⁶ A. C. Clairaut,⁷ P. L. Maupertuis,⁸ F. Nicole,⁹ Ch. de Montigny,¹⁰ Le Marquis de Courtivron,¹¹ J. d'Alembert,¹² N. C. de Condorcet,¹³ J. Lagrange.¹⁴ These illustrations show that about the middle of the eighteenth century parentheses were making vigorous inroads upon the territory previously occupied in France by vinculum almost exclusively.

353. *Terms in an aggregate placed in a vertical column.*—The employment of a brace to indicate the sum of coefficients or factors placed in a column was in vogue with Vieta (§ 176), Descartes, and many other writers. Descartes in 1637 used a single brace,¹ as in

$$\left. \begin{array}{r} x^4 - 2ax^3 + 2aa \\ - cc \end{array} \right\} xx - 2a^3x + a^4 \approx 0,$$

or a vertical bar² as in

$$\left. \begin{array}{r} x^4 + \frac{1}{2}aa \\ - cc \end{array} \right| \left. \begin{array}{r} zz - a^3 \\ - acc \end{array} \right| z + \frac{5}{16}a^4 \approx 0.$$

Wallis³ in 1685 puts the equation $aaa + baa + cca = ddd$, where a is the unknown, also in the form

$$\left. \begin{array}{r} 1 \\ aaa \end{array} \right| + \left. \begin{array}{r} b \\ aa \end{array} \right| + \left. \begin{array}{r} cc \\ a \end{array} \right| = \left. \begin{array}{r} ddd \\ 1 \end{array} \right|.$$

Sometimes terms containing the same power of x were written in a column without indicating the common factor or the use of symbols of aggregation; thus, John Wallis⁴ writes in 1685,

$$\begin{array}{r} aaa + baa + bca = +bcd \\ + caa - bda \\ - daa - cda \end{array}$$

Giovanni Poleni⁵ writes in 1729,

$$\begin{array}{r} y^6 + xxy^4 - 2ax^3yy + aax^4 = 0 \\ - 2axy^4 + aaxxyy \\ - aay^4 \end{array}$$

The use of braces for the combination of terms arranged in columns has passed away, except perhaps in recording the most unusual algebraic expressions. The tendency has been, whenever possible, to discourage symbolism spreading out vertically as well as horizontally. Modern printing encourages progression line by line.

354. *Marking binomial coefficients.*—In the writing of the factors in binomial coefficients and in factorial expressions much diversity of practice prevailed during the eighteenth century, on the matter of

the priority of operations indicated by $+$ and $-$, over the operations of multiplication marked by \cdot and \times . In $n \cdot n - 1 \cdot n - 2$ or $n \times n - 1 \times n - 2$, or $n, n - 1, n - 2$, it was understood very generally that the subtractions are performed first, the multiplications later, a practice contrary to that ordinarily followed at that time. In other words, these expressions meant $n(n-1)(n-2)$. Other writers used parentheses or vinculum, which removed all inconsistency and ambiguity. Nothing was explicitly set forth by early writers which would attach different meanings to nn and $n \cdot n$ or $n \times n$. And yet, $n \cdot n - 1 \cdot n - 2$ was not the same as $nn - 1n - 2$. Consecutive dots or crosses tacitly conveyed the idea that what lies between two of them must be aggregated as if it were inclosed in a parenthesis. Some looseness in notation occurs even before general binomial coefficients were introduced. Isaac Barrow¹ wrote " $L - M \times : R + S$ " for $(L - M)(R + S)$, where the colon designated aggregation, but it was not clear that $L - M$, as well as $R + S$, were to be aggregated. In a manuscript of Leibniz² one finds the number of combinations of n things, taken k at a time, given in the form

$$\frac{n \frown n - 1 \frown n - 2, \text{ etc.}, n - k + 1}{1 \frown 2 \frown 3, \text{ etc.}, \frown k}.$$

This diversity in notation continued from the seventeenth down into the nineteenth century. Thus, Major Edward Thorncroft (1704)³ writes $m \times m - 1 \times m - 2 \times m - 3$, etc. A writer⁴ in the *Acta eruditorum* gives the expression $n, n - 1$. Another writer⁵ gives $\frac{(n, n - 1, n - 2)}{2, 3}$. Leibniz's⁶ notation, as described in 1710 (§ 198), contains $e \cdot e - 1 \cdot e - 2$ for $e(e - 1)(e - 2)$. Johann Bernoulli⁷ writes $n \cdot n - 1 \cdot n - 2$. This same notation is used by Jakob (James) Bernoulli⁸ in a

posthumous publication, by F. Nicole¹ who uses $x+n \cdot x+2n \cdot x+3n$, etc., by Stirling² in 1730, by Cramer³ who writes in a letter to J. Stirling $a \cdot a+b \cdot a+2b$, by Nicolaus Bernoulli⁴ in a letter to Stirling $r \cdot r+b \cdot r+2b$... by Daniel Bernoulli⁵ $l-1 \cdot l-2$, by Lambert⁶ $4m-1 \cdot 4m-2$, and by König⁷ $n \cdot n-5 \cdot n-6 \cdot n-7$. Euler⁸ in 1764 employs in the same article two notations: one, $n-5 \cdot n-6 \cdot n-7$; the other, $n(n-1)(n-2)$. Condorcet⁹ has $n+2 \times n+1$. Hindenburg¹⁰ of Göttingen uses round parentheses and brackets, nevertheless he writes binomial factors thus, $m \cdot m-1 \cdot m-2 \dots m-s+1$. Segner¹¹ and Ferroni¹² write $n \cdot n-1 \cdot n-2$. Cossali¹³ writes $4 \times -2 = -8$. As late as 1811 A. M. Legendre¹⁴ has $n \cdot n-1 \cdot n-2 \dots 1$.

On the other hand, F. Nicole,¹⁵ who in 1717 avoided vinculum, writes in 1723, $x \cdot n + n \cdot x + 2n$, etc. Stirling¹⁶ in 1730 adopts $z-1 \cdot z-2$. De Moivre¹⁷ in 1730 likewise writes $m-p \times m-q \times m-s$, etc. Similarly, Dodson,¹⁸ $n \cdot n-1 \cdot n-2$, and the Frenchman F. de Lalande,¹⁹

$m \cdot (m+1) \cdot (m+2)$. In Lagrange¹ we encounter in 1772 the strictly modern form $(m+1)(m+2)(m+3), \dots$, in Laplace² in 1778 the form $(i-1) \cdot (i-2) \dots (i-r+1)$.

The omission of parentheses unnecessarily aggravates the interpretation of elementary algebraic expressions, such as are given by Kirkman,³ viz., $-3=3 \times -1$ for $-3=3 \times (-1)$, $-m \times -n$ for $(-m)(-n)$.

355. *Special uses of parentheses*.—A use of round parentheses and brackets which is not strictly for the designation of aggregation is found in Cramer⁴ and some of his followers. Cramer in 1750 writes two equations involving the variables x and y thus:

$$\begin{aligned} A \dots x' - [-1]x^{n-1} + [1^2]x^{n-2} - [1^3]x^{n-3} + \&c. \dots [1^n] = 0, \\ B \dots (0)x^o + (1)x' + (2)x^2 + (3)x^3 + \&c. \dots + (m)x^m = 0, \end{aligned}$$

where $1, 1^2, 1^3, \dots$, within the brackets of equation A do not mean powers of unity, but the coefficients of x , which are rational functions of y . The figures $0, 1, 2, 3$, in B are likewise coefficients of x and functions of y . In the further use of this notation, (02) is made to represent the product of (0) and (2) ; (30) the product of (3) and (0) , etc. Cramer's notation is used in Italy by Cossali⁵ in 1799.

Special uses of parentheses occur in more recent time. Thus W. F. Sheppard⁶ in 1912 writes

$$\begin{aligned} (n, r) \text{ for } n(n-1) \dots (n-r+1)/r! \\ [n, r] \text{ for } n(n+1) \dots (n+r-1)/r! \\ (n, 2s+1) \text{ for } (n-s)(n-s+1) \dots (n+s)/(2s+1)! \end{aligned}$$

356. *A star to mark the absence of terms*.—We find it convenient to discuss this topic at this time. René Descartes, in *La Géométrie* (1637), arranges the terms of an algebraic equation according to the descending order of the powers of the unknown quantity x, y , or z . If any power of the unknown below the highest in the equation is

⁶ W. F. Sheppard in *Fifth International Mathematical Congress*, Vol. II, p. 355.

lacking, that fact is indicated by a *, placed where the term would have been. Thus, Descartes writes $x^6 - a^4bx = 0$ in this manner:¹

$$x^6 * * * * - - a^4bx^* = 0.$$

He does not explain why there was need of inserting these stars in the places of the missing terms. But such a need appears to have been felt by him and many other mathematicians of the seventeenth and eighteenth centuries. Not only were the stars retained in later editions of *La Géométrie*, but they were used by some but not all of the leading mathematicians, as well as by many compilers of textbooks. Kinckhuysen² writes " $x^5 * * * * - b = 0$." Prestet³ in 1675 writes $a^{3**} + b^3$, and retains the * in 1689. The star is used by Baker,⁴ Varignon,⁵ John Bernoulli,⁶ Alexander,⁷ A. de Graaf,⁸ E. Halley.⁹ Fr. van Schooten used it not only in his various Latin editions of Descartes' *Geometry*, but also in 1646 in his *Conic Sections*,¹⁰ where he writes $z^3 \propto * - pz + q$ for $z^3 = -pz + q$. In W. Whiston's¹¹ 1707 edition of I. Newton's *Universal Arithmetick* one reads $aa^* - bb$ and the remark "... locis vacuis substituitur nota *." Raphson's English 1728 edition of the same work also uses the *. Jones¹² uses * in 1706, Reyneau¹³ in 1708; Simpson¹⁴ employs it in 1737 and Waring¹⁵ in 1762. De Lagny¹⁶

employs it in 1733, De Gua¹ in 1741, MacLaurin² in his *Algebra*, and Fenn³ in his *Arithmetic*. But with the close of the eighteenth century the feeling that this notation was necessary for the quick understanding of elementary algebraic polynomials passed away. In more advanced fields the star is sometimes encountered in more recent authors. Thus, in the treatment of elliptic functions, Weierstrass⁴ used it to mark the absence of a term in an infinite series, as do also Greenhill⁵ and Fricke.⁶

IV

SYMBOLS IN GEOMETRY

(ELEMENTARY PART)

A. ORDINARY ELEMENTARY GEOMETRY

357. The symbols sometimes used in geometry may be grouped roughly under three heads: (1) pictographs or pictures representing geometrical concepts, as \triangle representing a triangle; (2) ideographs designed especially for geometry, as \sim for "similar"; (3) symbols of elementary algebra, like $+$ and $-$.

Early use of pictographs.—The use of geometrical drawings goes back at least to the time of Ahmes, but the employment of pictographs in the place of words is first found in Heron's *Dioptra*. Heron (150 A.D.) wrote \triangle for triangle, \parallel for parallel and parallelogram, also $\underline{\parallel}$ for parallelogram, \square for rectangle, \bigcirc for circle.¹ Similarly, Pappus (fourth century A.D.) writes \bigcirc and \odot for circle, ∇ and \triangle for triangle, \perp for right angle, $\underline{\parallel}$ or \equiv for parallel, \square for square.² But these were very exceptional uses not regularly adopted by the authors and occur in few manuscripts only. They were not generally known and are not encountered in other mathematical writers for about one thousand years. Paul Tannery calls attention to the use of the symbol \square in a medieval manuscript to represent, not a square foot, but a cubic foot; Tannery remarks that this is in accordance with the ancient practice of the Romans.³ This use of the square is found in the *Triparty* of Chuquet (§ 132) and in the arithmetic of De la Roche.

358. Geometric figures were used in astrology to indicate roughly the relative positions of two heavenly bodies with respect to an observer. Thus δ , ρ , \square , \triangle , $*$ designated,⁴ respectively, conjunction,

¹ *Notices et extraits des manuscrits de la Bibliothèque impériale*, Vol. XIX, Part II (Paris, 1858), p. 173.

³ Paul Tannery, *Mémoires scientifiques*, Vol. V (Toulouse and Paris, 1922), p. 73.

⁴ Kepler says: "Quot sunt igitur aspectus? Vetus astrologia agnoscit tantum quinque: conjunctionem (δ), cum radii planetarum binorum in Terram descendentes in unam conjunguntur lineam; quod est veluti principium aspectuum omnium. 2) Oppositionem (ρ), cum bini radii sunt ejusdem rectae partes, seu

opposition, at right angles, at 120° , at 60° . These signs are reproduced in Christian Wolff's *Mathematisches Lexicon* (Leipzig, 1716), page 188. The \ast , consisting of three bars crossing each other at 60° , was used by the Babylonians to indicate degrees. Many of their war carriages are pictured as possessing wheels with six spokes.¹

359. In Plato of Tivoli's translation (middle of twelfth century) of the *Liber embadorum* by Savasorda who was a Hebrew scholar, at Barcelona, about 1100 A.D., one finds repeatedly the designations \widehat{abc} , \widehat{ab} for arcs of circles.² In 1555 the Italian Fr. Maurolycus³ employs \triangle , \square , also \ast for hexagon and $\cdot\therefore$ for pentagon, while in 1575 he also used \square . About half a century later, in 1623, Metius in the Netherlands exhibits a fondness for pictographs and adopts not only \triangle , \square , but a circle with a horizontal diameter and small drawings representing a sphere, a cube, a tetrahedron, and an octohedron. The last four were never considered seriously for general adoption, for the obvious reason that they were too difficult to draw. In 1634, in France, Hérigone's *Cursus mathematicus* (§ 189) exhibited an eruption of symbols, both pictographs and arbitrary signs. Here is the sign $<$ for angle, the usual signs for triangle, square, rectangle, circle, also \perp for right angle, the Heronic $=$ for parallel, \diamond for parallelogram, \frown for arc of circle, \ominus for segment, $-$ for straight line, \perp for perpendicular, $5<$ for pentagon, $6<$ for hexagon.

In England, William Oughtred introduced a vast array of characters into mathematics (§§ 181–85); over forty of them were used in symbolizing the tenth book of Euclid's *Elements* (§§ 183, 184), first printed in the 1648 edition of his *Clavis mathematicae*. Of these symbols only three were pictographs, namely, \square for rectangle, \square for square, \triangle for triangle (§ 184). In the first edition of the *Clavis* (1631), the \square alone occurs. In the *Trigonometria* (1657), he employed \angle for angle and \sphericalangle for angles (§ 182), \parallel for parallel occurs in Oughtred's

cum duae quartae partes circuli a binis radiis interceptae sunt, id est unus semicirculus. 3) Tetragonum seu quadratum (\square), cum una quarta. 4) Trigonum seu trinum (\triangle), cum una tertia seu duae sextae. 5) Hexagonum seu sextilem (\ast), cum una sexta." See Kepler, *Opera omnia* (ed. Ch. Frisch), Vol. VI (1866), p. 490, quoted from "Epitomes astronomiae" (1618).

Opuscula mathematica hactenus inedita (1677), a posthumous work (§ 184).

Klügel¹ mentions a cube \square as a symbol attached to cubic measure, corresponding to the use of \square in square measure.

Euclid in his *Elements* uses lines as symbols for magnitudes, including numbers,² a symbolism which imposed great limitations upon arithmetic, for he does not add lines to squares, nor does he divide a line by another line.

360. *Signs for angles*.—We have already seen that Hérigone adopted $<$ as the sign for angle in 1634. Unfortunately, in 1631, Harriot's *Artis analyticae praxis* utilized this very symbol for "less than." Harriot's $>$ and $<$ for "greater than" and "less than" were so well chosen, while the sign for "angle" could be easily modified so as to remove the ambiguity, that the change of the symbol for angle was eventually adopted. But $<$ for angle persisted in its appearance, especially during the seventeenth and eighteenth centuries. We find it in W. Leybourn,³ J. Kersey,⁴ E. Hatton,⁵ E. Stone,⁶ J. Hodgson,⁷ D'Alembert's *Encyclopédie*,⁸ Hall and Steven's *Euclid*,⁹ and Th. Reye.¹⁰ John Caswell¹¹ used the sign \angle to express "equiangular."

A popular modified sign for angle was \angle , in which the lower stroke is horizontal and usually somewhat heavier. We have encountered this in Oughtred's *Trigonometria* (1657), Caswell,¹² Dulaurens,¹³

Jones,¹ Emerson,² Hutton,³ Fuss,⁴ Steenstra,⁵ Klügel,⁶ Playfair,⁷ Kambly,⁸ Wentworth,⁹ Fiedler,¹⁰ Casey,¹¹ Lieber and von Lühmann,¹² Byerly,¹³ Müller,¹⁴ Mehler,¹⁵ C. Smith,¹⁶ Beman and Smith,¹⁷ Layng,¹⁸ Hopkins,¹⁹ Robbins,²⁰ the National Committee (in the U.S.A.).²¹ The plural "angles" is designated by Caswell $\angle \angle$; by many others thus, Δ . Caswell also writes $Z \angle \angle$ for the "sum of two angles," and $X \angle \angle$ for the "difference of two angles." From these quotations it is evident that the sign \angle for angle enjoyed wide popularity in different countries. However, it had rivals.

361. Sometimes the same sign is inverted, thus ∇ as in John Ward.²² Sometimes it is placed so as to appear \wedge , as in the *Ladies*

*Diary*¹ and in the writings of Reyer,² Bolyai,³ and Ottoni.⁴ This position is widely used in connection with one or three letters marking an angle. Thus, the angle ABC is marked by L. N. M. Carnot⁵ \widehat{ABC} in his *Géométrie de position* (1803); in the *Penny Cyclopædia* (1839), article "Sign," there is given $\widehat{A}B$; Binet,⁶ Möbius,⁷ and Favaro⁸ wrote \widehat{ab} as the angle formed by two straight lines a and b ; Favaro wrote also \widehat{PDC} . The notation $\widehat{a}b$ is used by Stolz and Gmeiner,⁹ so that $\widehat{a}b = -\widehat{b}a$; Nixon¹⁰ adopted \widehat{A} , also \widehat{ABC} ; the designation \widehat{APM} is found in Enriques,¹¹ Borel,¹² and Durrell.¹³

362. Some authors, especially German, adopted the sign \times for angle. It is used by Spitz,¹⁴ Fiedler,¹⁵ Halsted,¹⁶ Milinowski,¹⁷ Meyer,¹⁸

Fialkowski,¹ Henrici and Treutlein,² Brückner,³ Doehlemann,⁴ Schur,⁵ Bernhard,⁶ Auerbach and Walsh,⁷ Mangoldt.⁸

If our quotations are representative, then this notation for angle finds its adherents in Germany and the United States. A slight modification of this sign is found in Byrne⁹ \triangleleft .

Among sporadic representations of angles are the following: The capital letter¹⁰ L , the capital letter¹¹ V , or that letter inverted,¹² Λ , the inverted capital letter¹³ ∇ ; the perpendicular lines¹⁴ \perp or \bot , \overline{pq} the angle made by the lines¹⁵ p and q , (ab) the angle between the rays,¹⁶ a and b , \widehat{ab} the angle between the lines¹⁷ a and b , or (u, v) the angle¹⁸ formed by u and v .

363. Passing now to the designation of special angles we find \sphericalangle used to designate an oblique angle.¹⁹ The use of a pictograph for the designation of right angles was more frequent in former years than now and occurred mainly in English texts. The two perpendicular lines \perp to designate "right angle" are found in Reyher;²⁰ he lets

∠A stand for "angle A is a right angle," a symbolism which could be employed in any language. The vertical bar stands for equality (§ 263). The same idea is involved in the signs $a \uparrow b$, i.e., "angle a is equal to angle b ." The sign \perp for right angle is found in Jones,¹ Hatton,² Saverien,³ Fenn,⁴ and Steenstra.⁵ Kersey⁶ uses the sign \perp , Byrne⁷ \sqcap . Mach⁸ marks right angles \perp . The Frenchman Hérigone⁹ used the sign \perp , the Englishman Dupius¹⁰ \neg for right angle.

James Mills Peirce,¹¹ in an article on the notation of angles, uses "Greek letters to denote the *directions* of lines, without reference to their length. Thus if ρ denotes the axis in a system of polar co-ordinates, the polar angle will be $\check{\rho}$." Accordingly, $\beta_a = -\frac{\alpha}{\beta}$.

More common among more recent American and some English writers is the designation "rt. \angle " for right angle. It is found in G. A. Wentworth,¹² Byerly's *Chauvenet*,¹³ Hall and Stevens,¹⁴ Beman and Smith,¹⁵ Hopkins,¹⁶ Robbins,¹⁷ and others.

Some writers use instead of pictographs of angles abbreviations of the word. Thus Legendre¹⁸ sometimes writes "Angl. ACB ";

A. von Frank,¹ "*Wkl*," the abbreviation for *Winkel*, as in "*Wkl DOQ*."

The advent of non-Euclidean geometry brought Lobachevski's notation $\Pi(\rho)$ for angle of parallelism.²

The sign $\underline{=}$ to signify equality of the angles, and $\underline{=}$ to signify the equality of the sides of a figure, are mentioned in the article "*Caractere*" by D'Alembert in Diderot's *Encyclopédie* of 1754 and of 1781³ and in the Italian translation of the mathematical part (1800); also in Rees's *Cyclopaedia* (London, 1819), article "*Characters*," and in E. Stone's *New Mathematical Dictionary* (London, 1726), article "*Characters*," but Stone defines $\underline{=}$ as signifying "equiangular or similar." The symbol is given also by a Spanish writer as signifying *angulos iguales*.⁴ The sign $=^\circ$ to signify "equal number of degrees" is found in Palmer and Taylor's *Geometry*,⁵ but failed to be recommended as a desirable symbol in elementary geometry by the National Committee on Mathematical Requirements (1923), in their *Report*, page 79.

Halsted suggested the sign \angle for spherical angle and also the letter Ω to represent a "stereon," the unit of solid angle.⁶

364. *Signs for "perpendicular."*—The ordinary sign to indicate that one line is perpendicular to another, \perp , is given by Hérigone⁷ in 1634 and 1644. Another Frenchman, Dulaurens,⁸ used it in 1667. In 1673 Kersey⁹ in England employed it. The inverted capital letter \perp was used for this purpose by Caswell,¹⁰ Jones,¹¹ Wilson,¹² Saverien,¹³

and Mauduit.¹ Emerson² has the vertical bar extremely short, \perp . In the nineteenth century the symbol was adopted by all writers using pictographs in geometry. Sometimes \perp was used for "perpendiculars." Thomas Baker³ adopted the symbol \lrcorner for perpendicular.

365. *Signs for triangle, square, rectangle, parallelogram.*—The signs \triangle , \square , \square or \square , \square are among the most widely used pictographs. We have already referred to their occurrence down to the time of Hérigone and Oughtred (§ 184). The \square for parallelogram is of rare occurrence in geometries preceding the last quarter of the nineteenth century, while the \triangle , \square , and \square occur in van Schooten,⁴ Dulaurens,⁵ Kersey,⁶ Jones,⁷ and Saverien.⁸ Some authors use only two of the three. A rather curious occurrence is the Hebrew letter "mem," \beth , to represent a rectangle; it is found in van Schooten,⁹ Jones,¹⁰ John Alexander,¹¹ John I Bernoulli,¹² Ronayne,¹³ Klügel's *Wörterbuch*,¹⁴ and De Graaf.¹⁵ Newton,¹⁶ in an early manuscript tract on fluxions (October, 1666), indicates the area or fluent of a curve by prefixing a rectangle to the ordinate (§ 622), thus $\square \frac{axx-x^3}{ab+xx}$, where x is the abscissa, and the fraction is the ordinate.

After about 1880 American and English school geometries came to employ less frequently the sign \square for rectangle and to introduce more often the sign \square for parallelogram. Among such authors are

Halsted,¹ Wentworth,² Byerly,³ in his edition of Chauvenet, Beman and Smith,⁴ Layng,⁵ Nixon,⁶ Hopkins,⁷ Robbins,⁸ and Lyman.⁹ Only seldom do both \square and \sqsubset appear in the same text. Halsted¹⁰ denotes a parallelogram by $\parallel g'm$.

Special symbols for right and oblique spherical triangles, as used by Jean Bernoulli in trigonometry, are given in Volume II, § 524.

366. *The square as an operator.*—The use of the sign \square to mark the operation of squaring has a long history, but never became popular. Thus N. Tartaglia¹¹ in 1560 denotes the square on a line tc in the expression “il \square de. tc .” Cataldi¹² uses a black square to indicate the square of a number. Thus, he speaks of $8\frac{1}{4}$, “il suo \blacksquare è $75\frac{1}{16}$.” Stampioen¹³ in 1640 likewise marks the square on BC by the “ $\square BC$.” Caramvel¹⁴ writes “ $\square 25$. est Quadratum Numeri 25. hoc est, 625.”

A. de Graaf¹⁵ in 1672 indicates the square of a binomial thus: $\sqrt{a} \pm \sqrt{b}$, “ $zijn \square$ is $a+b \pm 2\sqrt{ab}$.” Johann I Bernoulli¹⁶ wrote $3 \square \sqrt[3]{ax+xx}$ for $3\sqrt{(ax+x^2)^2}$. Jakob Bernoulli in 1690¹⁷ designated

the square of $\frac{5}{8}$ by $\square\frac{5}{8}$, but in his collected writings¹ it is given in the modern form $(\frac{5}{8})^2$. Sometimes a rectangle, or the Hebrew letter "mem," is used to signify the product of two polynomials.²

367. *Sign for circle*.—Although a small image of a circle to take the place of the word was used in Greek time by Heron and Pappus, the introduction of the symbol was slow. Hérigone used \odot , but Oughtred did not. One finds \odot in John Kersey,³ John Caswell,⁴ John Ward,⁵ P. Steenstra,⁶ J. D. Blassière,⁷ W. Bolyai,⁸ and in the writers of the last half-century who introduced the sign \square for parallelogram. Occasionally the central dot is omitted and the symbol \bigcirc is used, as in the writings of Reyher⁹ and Saverien. Others, Fenn for instance, give both \bigcirc and \odot , the first to signify circumference, the second circle (area). Caswell¹⁰ indicates the perimeter by $\dot{\bigcirc}$. Metius¹¹ in 1623 draws the circle and a horizontal diameter to signify *circulus*.

368. *Signs for parallel lines*.—Signs for parallel lines were used by Heron and Pappus (§ 701); Hérigone used horizontal lines = (§ 189) as did also Dulaurens¹² and Reyher,¹³ but when Recorde's sign of equality won its way upon the Continent, vertical lines came to be used for parallelism. We find $||$ for "parallel" in Kersey,¹⁴ Caswell, Jones,¹⁵ Wilson,¹⁶ Emerson,¹⁷ Kambly,¹⁸ and the writers of the last

fifty years who have been already quoted in connection with other pictographs. Before about 1875 it does not occur as often as do Δ , \square , \square . Hall and Stevens¹ use "par^l or ||" for parallel. Kambly² mentions also the symbols $\#$ and \neq for parallel.

A few other symbols are found to designate parallel. Thus John Bolyai in his *Science Absolute of Space* used $|||$. Karsten³ used $\#$; he says: "Man pflege wohl das Zeichen $\#$ statt des Worts: *Parallel* der Kürze wegen zu gebrauchen." This use of that symbol occurs also in N. Fuss.⁴ Thomas Baker⁵ employed the sign \approx .

With Kambly $\#$ signifies rectangle. Häsel⁶ employs $\#$ as "the sign of parallelism of two lines or surfaces."

369. *Sign for equal and parallel*.— $\#$ is employed to indicate that two lines are equal and parallel in Klügel's *Wörterbuch*,⁷ it is used by H. G. Grassmann,⁸ Lorey,⁹ Fiedler,¹⁰ Henrici and Treutlein.¹¹

370. *Signs for arcs of circles*.—As early a writer as Plato of Tivoli (§ 359) used \widehat{ab} to mark the arc ab of a circle. Ever since that time it has occurred in geometric books, without being generally adopted. It is found in Hérigone,¹² in Reyher,¹³ in Kambly,¹⁴ in Lieber and Lühmann.¹⁵ W. R. Hamilton¹⁶ designated by $\frown LF$ the arc "from F to L ." These

references indicate the use of \frown to designate arc in different countries. In more recent years it has enjoyed some popularity in the United States, as is shown by its use by the following authors: Halsted,¹ Wells,² Nichols,³ Hart and Feldman,⁴ and Smith.⁵ The National Committee on Mathematical Requirements, in its *Report* (1923), page 78, is of the opinion that "the value of the symbol \frown in place of the short word *arc* is doubtful."

In 1755 John Landen⁶ used the sign $(P\hat{Q}R)$ for the circular arc which measures the angle $P\hat{Q}R$, the radius being unity.

371. *Other pictographs*.—We have already referred to Hérigone's use (§ 189) of $5<$ and $6<$ to represent pentagons and hexagons. Reyher actually draws a pentagon. Occasionally one finds a half-circle and a diameter \supset to designate a segment, and a half-circle without marking its center or drawing its diameter to designate an arc. Reyher in his *Euclid* draws \triangleleft for trapezoid.

Pictographs of solids are very rare. We have mentioned (§ 359) those of Metius. Saverein⁷ draws \blacksquare , \blacktriangle , \blacklozenge , \blacksquare to stand, respectively, for cube, pyramid, parallelopiped, rectangular parallelopiped, but these signs hardly belong to the category of pictographs. Dulaurens⁸ wrote \boxplus for cube and \boxplus for *aequi quadrimensum*. Joseph Fenn⁹ draws a small figure of a parallelopiped to represent that solid, as Metius had done. Halsted¹⁰ denotes symmetry by \div .

Some authors of elementary geometries have used algebraic symbols and no pictographs (for instance, Isaac Barrow, Karsten, Tacquet, Leslie, Legendre, Playfair, Chauvenet, B. Peirce, Todhunter), but no author since the invention of symbolic algebra uses pictographs without at the same time availing himself of algebraic characters.

372. *Signs for similarity and congruence*.—The designation of "similar," "congruent," "equivalent," has brought great diversity of notation, and uniformity is not yet in sight.

Symbols for similarity and congruence were invented by Leibniz.

In Volume II, § 545, are cited symbols for “coincident” and “congruent” which occur in manuscripts of 1679 and were later abandoned by Leibniz. In the manuscript of his *Characteristica Geometrica* which was not published by him, he says: “similitudinem ita notabimus: $a \sim b$.”¹ The sign is the letter *S* (first letter in *similis*) placed horizontally. Having no facsimile of the manuscript, we are dependent upon the editor of Leibniz’ manuscripts for the information that the sign in question was \sim and not \simeq . As the editor, C. I. Gerhardt, interchanged the two forms (as pointed out below) on another occasion, we do not feel certain that the reproduction is accurate in the present case. According to Gerhardt, Leibniz wrote in another manuscript \simeq for congruent. Leibniz’ own words are reported as follows: “ $ABC \simeq CDA$. Nam \sim mihi est signum similitudinis, et $=$ aequalitatis, unde congruentiae signum compono, quia quae simul et similia et aequalia sunt, ea congrua sunt.”² In a third manuscript Leibniz wrote $|\simeq|$ for coincidence.

An anonymous article printed in the *Miscellanea Berolinensia* (Berlin, 1710), under the heading of “Monitum de characteribus algebraicis,” page 159, attributed to Leibniz and reprinted in his collected mathematical works, describes the symbols of Leibniz; \sim for similar and \simeq for congruent (§ 198). Note the change in form; in the manuscript of 1679 Leibniz is reported to have adopted the form \sim , in the printed article of 1710 the form given is \simeq . Both forms have persisted in mathematical writings down to the present day. As regards the editor Gerhardt, the disconcerting fact is that in 1863 he reproduces the \simeq of 1710 in the form³ \sim .

The Leibnizian symbol \sim was early adopted by Christian von Wolf; in 1716 he gave \sim for *Aehnlichkeit*,⁴ and in 1717 he wrote “ $=$ et \sim ” for “equal and similar.”⁵ These publications of Wolf are the earliest in which the sign \sim appears in print. In the eighteenth and early part of the nineteenth century, the Leibnizian symbols for “similar” and “congruent” were seldom used in Europe and not at all in England and America. In England \sim or \simeq usually expressed “difference,” as defined by Oughtred. In the eighteenth century the signs for congruence occur much less frequently even than the signs

or similar. We have seen that Leibniz' signs for congruence did not use both lines occurring in the sign of equality $=$. Wolf was the first to use explicitly \sim and $=$ for congruence, but he did not combine the two into one symbolism. That combination appears in texts of the latter part of the eighteenth century. While the \cong was more involved, since it contained one more line than the Leibnizian \simeq , it had the advantage of conveying more specifically the idea of congruence as the superposition of the ideas expressed by \sim and $=$. The sign \sim or "similar" occurs in Camus' geometry,¹ \simeq for "similar" in A. R. Mauduit's conic sections² and in Karsten,³ \sim in Blassière's geometry,⁴ \cong for congruence in Häseler's⁵ and Reinhold's geometries,⁶ \simeq for similar in Diderot's *Encyclopédie*,⁷ and in Lorenz' geometry.⁸ In Klügel's *Wörterbuch*⁹ one reads, " \simeq with English and French authors means difference"; "with German authors \simeq is the sign of similarity"; Leibniz and Wolf have first used it." The signs \sim and \cong are used by Mollweide;¹⁰ \sim by Steiner¹¹ and Koppe;¹² \simeq is used by Prestel,¹³ \cong by Spitz;¹⁴ \sim and \cong are found in Lorey's geometry,¹⁵ Kambly's

Planimetrie,¹ and texts by Frischauf² and Max Simon.³ Lorey's book contains also the sign \cong a few times. Peano⁴ uses \sim for "similar" also in an arithmetical sense for classes. Perhaps the earliest use of \sim and \cong for "similar" and "congruent" in the United States are by G. A. Hill⁵ and Halsted.⁶ The sign \sim for "similar" is adopted by Henrici and Treutlein,⁷ \cong by Fiedler,⁸ \sim by Fialkowski,⁹ \sim by Beman and Smith.¹⁰ In the twentieth century the signs entered geometries in the United States with a rush: \cong for "congruent" were used by Busch and Clarke,¹¹ \cong by Meyers,¹² \cong by Slaught and Lennes,¹³ \sim by Hart and Feldman,¹⁴ \cong by Shutts,¹⁵ E. R. Smith,¹⁶ Wells and Hart,¹⁷ Long and Brenke,¹⁸ \cong by Auerbach and Walsh.¹⁹

That symbols often experience difficulty in crossing geographic or national boundaries is strikingly illustrated in the signs \sim and \cong . The signs never acquired a foothold in Great Britain. To be sure, the symbol \sim was adopted at one time by a member of the University

of Cambridge,¹ to express "is similar to" in an edition of Euclid. The book was set up in type, but later the sign was eliminated from all parts, except one. In a footnote the student is told that "in writing out the propositions in the Senate House, Cambridge, it will be advisable not to make use of this symbol, but merely to write the word short, thus, *is simil.*" Moreover, in the Preface he is informed that "more competent judges than the editor" advised that the symbol be eliminated, and so it was, except in one or two instances where "it was too late to make the alteration," the sheets having already been printed. Of course, one reason for failure to adopt \sim for "similar" in England lies in the fact that \sim was used there for "difference."

373. When the sides of the triangle ABC and $A'B'C'$ are considered as being vectors, special symbols have been used by some authors to designate different kinds of similarity. Thus, Stolz and Gmeiner² employ \approx to mark that the similar triangles are uniformly similar (*einstimmig ähnlich*), that is, the equal angles of the two triangles are all measured clockwise, or all counter-clockwise; they employ \simeq to mark that the two triangles are symmetrically similar, that is, of two numerically equal angles, one is measured clockwise and the other counter-clockwise.

The sign \sim has been used also for "is [or are] measured by," by Alan Sanders;³ the sign \cong is used for "equals approximately," by Hudson and Lipka.⁴ A. Pringsheim⁵ uses the symbolism $a_\nu \cong ab_\nu$ to express that $\lim_{\nu \rightarrow +\infty} \frac{a_\nu}{b_\nu} = a$.

374. The sign \cong for congruence was not without rivals during the nineteenth century. Occasionally the sign \equiv , first introduced by Riemann⁶ to express identity, or non-Gaussian arithmetical congruence of the type $(a+b)^2 \equiv a^2 + 2ab + b^2$, is employed for the expression of geometrical congruence. One finds \equiv for congruent in W. Bolyai,⁷

H. G. Grassmann,¹ Dupuis,² Budden,³ Veronese,⁴ Casey,⁵ Halsted,⁶ Baker,⁷ Betz and Webb,⁸ Young and Schwarz,⁹ McDougall.¹⁰ This sign \equiv for congruence finds its widest adoption in Great Britain at the present time. Jordan¹¹ employs it in analysis to express equivalence.

The idea of expressing similarity by the letter S placed in a horizontal position is extended by Callet, who uses ϖ , \supset , \mathfrak{S} , to express "similar," "dissimilar," "similar or dissimilar."¹² Callet's notation for "dissimilar" did not meet with general adoption even in his own country.

The sign \equiv has also other uses in geometry. It is used in the Riemannian sense of "identical to," not "congruent," by Busch and Clarke,¹³ Meyers,¹⁴ E. R. Smith,¹⁵ Wells and Hart.¹⁶ The sign \equiv or \times is made to express "equivalent to" in the *Geometry* of Hopkins.¹⁷

The symbols \sim and \simeq for "similar" have encountered some competition with certain other symbols. Thus "similar" is marked $|||$ in the geometries of Budden¹⁸ and McDougall.

The relation "coincides with," which Leibniz had marked with $|\underline{=}|$, is expressed by \neq in White's *Geometry*.¹⁹ Cremona²⁰ denotes by

$\alpha.BC \equiv A'$ that the point common to the plane α and the straight line BC coincides with the point A' . Similarly, a German writer¹ of 1851 indicates by $a \equiv b$, $A \equiv B$ that the two points a and b or the two straight lines A and B coincide (*zusammenfallen*).

375. *The sign \simeq for equivalence.*—In many geometries congruent figures are marked by the ordinary sign of equality, $=$. To distinguish between congruence of figures, expressed by $=$, and mere equivalence of figures or equality of areas, a new symbol \simeq came to be used for “equivalent to” in the United States. The earliest appearance of that sign known to us is in a geometry brought out by Charles Davies² in 1851. He says that the sign “denotes equivalency and is read *is equivalent to*.” The curved parts in the symbol, as used by Davies, are not semicircles, but semiellipses. The sign is given by Davies and Peck,³ Benson,⁴ Wells,⁵ Wentworth,⁶ McDonald,⁷ Macnie,⁸ Phillips and Fisher,⁹ Milne,¹⁰ McMahon,¹¹ Durell,¹² Hart and Feldman.¹³ It occurs also in the trigonometry of Anderegg and Roe.¹⁴ The signs \simeq and $=$ for equivalence and equality (i.e. congruence) are now giving way in the United States to $=$ and \cong or \triangleq .

We have not seen this symbol for equivalence in any European book. A symbol for equivalence, \triangleq , was employed by John Bolyai¹⁵ in cases like $AB \triangleq CD$, which meant $\angle CAB = \angle ACD$. That the line BN is parallel and equal to CP he indicated by the sign “ $BN || \triangleq CP$.”

376. *Lettering of geometric figures.*—Geometric figures are found in the old Egyptian mathematical treatise, the Ahmes papyrus (1550 B.C. or older), but they are not marked by signs other than numerals to indicate the dimensions of lines.

The designation of points, lines, and planes by a letter or by letters was in vogue among the Greeks and has been traced back¹ to Hippocrates of Chios (about 440 B.C.).

The Greek custom of lettering geometric figures did not find imitation in India, where numbers indicating size were written along the sides. However, the Greek practice was adopted by the Arabs, later still by Regiomontanus and other Europeans.² Gerbert³ and his pupils sometimes lettered their figures and at other times attached Roman numerals to mark lengths and areas. The Greeks, as well as the Arabs, Leonardo of Pisa, and Regiomontanus usually observed the sequence of letters *a, b, g, d, e, z*, etc., omitting the letters *c* and *f*. We have here the Greek-Arabic succession of letters of the alphabet, instead of the Latin succession. Referring to Leonardo of Pisa's *Practica geometriae* (1220) in which Latin letters are used with geometric figures, Archibald says: "Further evidence that Leonardo's work was of Greek-Arabic extraction can be found in the fact that, in connection with the 113 figures, of the section *On Divisions*, of Leonardo's work, the lettering in only 58 contains the letters *c* or *f*; that is, the Greek-Arabic succession *a b g d e z* is used almost as frequently as the Latin *a b c d e f g*; elimination of Latin letters added to a Greek succession in a figure, for the purpose of numerical examples (in which the work abounds), makes the balance equal."⁴

Occasionally one encounters books in which geometric figures are not lettered at all. Such a publication is Scheubel's edition of Euclid,⁵ in which numerical values are sometimes written alongside of lines as in the Ahmes papyrus.

An oddity in the lettering of geometric figures is found in Ramus' use⁶ of the vowels *a, e, i, o, u, y* and the employment of consonants only when more than six letters are needed in a drawing.

⁶ *P. Rami Scholarum mathematicorum libri vnus et triginta* (Basel, 1569).

In the designation of a group of points of equal rank or of the same property in a figure, resort was sometimes taken to the repetition of the same letter, as in the works of Gregory St. Vincent,¹ Blaise Pascal,² John Wallis,³ and Johann Bernoulli.⁴

377. The next advancement was the introduction of indices attached to letters, which proved to be an important aid. An apparently unconscious use of indices is found in Simon Stevin,⁵ who occasionally uses dotted letters \dot{B} , \ddot{B} to indicate points of equal significance obtained in the construction of triangles. In a German translation⁶ of Stevin made in 1628, the dots are placed beneath the letter B , $\underset{\cdot}{B}$. Similarly, Fr. van Schooten⁷ in 1649 uses designations for points:

$$C, 2C, 3C; S, 2S, 3S; T, 2T, 3T; V, 2V, 3V.$$

his procedure is followed by Leibniz in a letter to Oldenburg⁸ of August 27, 1676, in which he marks points in a geometric figure by 3 , $2B$, $3B$, $1D$, $2D$, $3D$. The numerals are here much smaller than the letters, but are placed on the same level with the letters (see also 549). This same notation is used by Leibniz in other essays⁹ and again in a treatise of 1677 where he lets a figure move so that in its new position the points are marked with double indices like $1\textcircled{D}$ and \textcircled{D} . In 1679 he introduced a slight innovation by marking the points of the principal curve $3b$, $6b$, $9b$. . . , generally $y\bar{b}$, the curves of the entire curve $\bar{y}b$. The point $3b$ when moved yields the points $3b$, $2\ 3b$, $3\ 3b$; the surface generated by $\bar{y}b$ is marked $\bar{z}yb$. Leibniz used indices also in his determinant notations (Vol. II, § 547).

I. Newton used dots and strokes for marking fluxions and fluents (§§ 567, 622). As will be seen, indices of various types occur repeatedly in specialized notations of later date. For example, L. Euler¹ used in 1748

$$\begin{array}{ccc} x' & x'' & x''' \\ y' & y'' & y''' \end{array}$$

as co-ordinates of points of equal significance. Cotes² used such strokes in marking successive arithmetical differences. Monge³ employed strokes, K' , K'' , K''' , and also ' K ', ' K '.

378. The introduction of different kinds of type received increased attention in the nineteenth century. Wolfgang Bolyai⁴ used Latin and Greek letters to signify quantities, and German letters to signify points and lines. Thus, \widetilde{ab} signifies a line ab infinite on both sides; $\widetilde{a}b$ a line starting at the point a and infinite on the side b ; $a\widetilde{b}$ a line starting at b and infinite on the side a ; \widetilde{P} a plane P extending to infinity in all directions.

379. A remarkable symbolism, made up of capital letters, lines, and dots, was devised by L. N. M. Carnot.⁵ With him, A, B, C, \dots marked points

$\overline{AB}, \widehat{AB}$	marked the segment AB and the circular arc AB
\overline{BCD}	marked that the points B, C, D are collinear, C being placed between B and D
$\overline{AB} \cdot \overline{CD}$	is the point of intersection of the indefinite lines AB, CD
\widehat{ABCD}	marked four points on a circular arc, in the order indicated
$\widehat{AB} \cdot \widehat{CD}$	is the point of intersection of the two arcs AB and CD
$F \overline{AB} \cdot \overline{CD}$	is the straight line which passes through the points F and $\overline{AB} \cdot \overline{CD}$

⁵ L. N. M. Carnot, *De la Corrélation des figures de géométrie* (Paris, an IX = 1801), p. 40–43.

$= =$	signifies equipollence, or identity of two objects
\bigwedge_{ABC}	marks the angle formed by the straight lines, AB , BC , B being the vertex
$\bigwedge_{AB \ CD}$	is the angle formed by the two lines AB and CD
$\triangle ABC$	the triangle having the vertices A , B , C
$\triangle ABC$	is a right triangle
\overline{ABC}	is the area of the triangle ABC

A criticism passed upon Carnot's notation is that it loses its clearness in complicated constructions.

Reye¹ in 1866 proposed the plan of using capital letters, A , B , C , for points; the small letters a , b , c , . . . , for lines; α , β , γ , . . . , for planes. This notation has been adopted by Favaro and others.² Besides, Favaro adopts the signs suggested by H. G. Grassmann,³ AB for a straight line terminating in the points A and B , Aa the plane passing through A and a , aa the point common to a and a ; ABC the plane passing through the points A , B , C ; $\alpha\beta\gamma$ the point common to the planes α , β , γ , and so on. This notation is adopted also by Cremona,⁴ and some other writers.

The National Committee on Mathematical Requirements (1923) recommends (*Report*, p. 78) the following practice in the lettering of geometric figures: "Capitals represent the vertices, corresponding small letters represent opposite sides, corresponding small Greek letters represent angles, and the primed letters represent the corresponding parts of a congruent or similar triangle. This permits speaking of α (alpha) instead of 'angle A ' and of 'small a ' instead of BC ."

380. *Sign for spherical excess*.—John Caswell writes the spherical excess $c = A + B + C - 180^\circ$ thus: " $E = \angle \angle \angle - 2 \perp$." Letting π stand for the periphery of a great circle, G for the surface of the sphere, R for the radius of the sphere, he writes the area \triangle of a spherical triangle thus:⁵

$$2\pi \triangle = EG = 2R\pi E,$$

$$\triangle = RE.$$

¹ Reye, *Geometrie der Lage* (Hannover, 1866), p. 7.

⁵ John Wallis, *Treatise of Algebra* (London, 1685), Appendix on "Trigonometry" by John Caswell, p. 15.

The letter *E* for spherical excess has retained its place in some books¹ to the present time. Legendre,² in his *Éléments de géométrie* (1794, and in later editions), represents the spherical excess by the letter *S*. In a German translation of this work, Crelle³ used for this excess the sign ε . Chauvenet⁴ used the letter *K* in his *Trigonometry*.

381. *Symbols in the statement of theorems.*—The use of symbols in the statement of geometric theorems is seldom found in print, but is sometimes resorted to in handwriting and in school exercises. It occurs, however, in William Jones's *Synopsis palmariorum*, a book which compresses much in very small space. There one finds, for instance, "An \angle in a Segment $>$, $=$, $<$ Semicircle is Acute, Right, Obtuse."⁵

To Julius Worpitzky (1835–95), professor at the Friedrich Werder Gymnasium in Berlin, is due the symbolism *S.S.S.* to recall that two triangles are congruent if their three sides are equal, respectively; and the abbreviations *S.W.S.*, *W.S.W.* for the other congruence theorems.⁶ Occasionally such abbreviations have been used in America, the letter *a* ("angle") taking the place of the letter *W* (*Winkel*), so that *asa* and *sas* are the abbreviations sometimes used. The National Committee on Mathematical Requirements, in its *Report* of 1923, page 79, discourages the use of these abbreviations.

382. *Signs for incommensurables.*—We have seen (§§ 183, 184) that Oughtred had a full set of ideographs for the symbolic representation of Euclid's tenth book on incommensurables. A different set of signs was employed by J. F. Lorenz⁷ in his edition of Euclid's *Elements*; he used the Latin letter *C* turned over, as in $A \supset B$, to indicate that *A* and *B* are commensurable; while $A \cup B$ signified that *A* and *B* are incommensurable; $A \cap B$ signified that the lines *A* and *B* are commensurable only in power, i.e., A^2 and B^2 are commensurable, while *A* and *B* were not; $A \sqcup B$, that the lines are incommensurable even in power, i.e., *A* and *B* are incommensurable, so are A^2 and B^2 .

383. *Unusual ideographs in elementary geometry.*—For “is measured by” there is found in Hart and Feldman’s *Geometry*¹ and in that of Auerbach and Walsh² the sign \propto , in Shutt’s *Geometry*³ the sign \perp . Veronese⁴ employs \equiv to mark “not equal” line segments.

A horizontal line drawn underneath an equation is used by Kambly⁵ to indicate *folglich* or “therefore”; thus:

$$\begin{array}{r} \angle r + q = 2R \\ \angle s + q = 2R \\ \hline \angle r + q = s + q \\ \hline \angle r = s \end{array}$$

384. *Algebraic symbols in elementary geometry.*—The use of algebraic symbols in the solution of geometric problems began at the very time when the symbols themselves were introduced. In fact, it was very largely geometrical problems which for their solution created a need of algebraic symbols. The use of algebraic symbolism in applied geometry is seen in the writings of Pacioli, Tartaglia, Cardan, Bombelli, Widman, Rudolff, Stifel, Stevin, Vieta, and writers since the sixteenth century.

It is noteworthy that printed works which contained pictographs had also algebraic symbols, but the converse was not always true. Thus, Barrow’s *Euclid* contained algebraic symbols in superabundance, but no pictographs.

The case was different in works containing a systematic development of geometric theory. The geometric works of Euclid, Archimedes, and Apollonius of Perga did not employ algebraic symbolism; they were purely rhetorical in the form of exposition. Not until the seventeenth century, in the writings of Hérigone in France, and Oughtred, Wallis, and Barrow in England, was there a formal translation of the geometric classics of antiquity into the language of syncopated or symbolic algebra. There were those who deplored this procedure; we proceed to outline the struggle between symbolists and rhetoricians.

PAST STRUGGLES BETWEEN SYMBOLISTS AND RHETORICIANS IN ELEMENTARY GEOMETRY

385. For many centuries there has been a conflict between individual judgments, on the use of mathematical symbols. On the one side are those who, in geometry for instance, would employ hardly any mathematical symbols; on the other side are those who insist on the use of ideographs and pictographs almost to the exclusion of ordinary writing. The real merits or defects of the two extreme views cannot be ascertained by a priori argument; they rest upon experience and must therefore be sought in the study of the history of our science.

The first printed edition of Euclid's *Elements* and the earliest translations of Arabic algebras into Latin contained little or no mathematical symbolism.¹ During the Renaissance the need of symbolism disclosed itself more strongly in algebra than in geometry. During the sixteenth century European algebra developed symbolisms for the writing of equations, but the arguments and explanations of the various steps in a solution were written in the ordinary form of verbal expression.

The seventeenth century witnessed new departures; the symbolic language of mathematics displaced verbal writing to a much greater extent than formerly. The movement is exhibited in the writings of three men: Pierre Hérigone² in France, William Oughtred³ in England, and J. H. Rahn⁴ in Switzerland. Hérigone used in his *Cursus mathematicus* of 1634 a large array of new symbols of his own design. He says in his Preface: "I have invented a new method of making demonstrations, brief and intelligible, without the use of any lan-

¹ Erhard Ratdolt's print of *Campanus' Euclid* (Venice, 1482). Al-Khowârizmî's algebra was translated into Latin by Gerard of Cremona in the twelfth century. It was probably this translation that was printed in Libri's *Histoire des sciences mathématique en Italie*, Vol. I (Paris, 1838), p. 253-97. Another translation into Latin, made by Robert of Chester, was edited by L. C. Karpinski (New York, 1915). Regarding Latin translations of Al-Khowârizmî, see also G. Eneström, *Bibliotheca mathematica* (3d ser.), Vol. V (1904), p. 404; A. A. Björnbo, *ibid.* (3d ser.), Vol. VII (1905), p. 239-48; Karpinski, *Bibliotheca mathematica* (3d ser.), Vol. XI, p. 125.

² Pierre Herigone, *op. cit.*, Vol. I-VI (Paris, 1634; 2d ed., 1644).

³ William Oughtred, *Clavis mathematicae* (London, 1631, and later editions); also Oughtred's *Circles of Proportion* (1632), *Trigonometrie* (1657), and minor works.

⁴ J. H. Rahn, *Teutsche Algebra* (Zürich, 1659), Thomas Brancker, *An Introduction to Algebra* (trans. out of the High-Dutch; London, 1668).

guage." In England, William Oughtred used over one hundred and fifty mathematical symbols, many of his own invention. In geometry Oughtred showed an even greater tendency to introduce extensive symbolisms than did Hérigone. Oughtred translated the tenth book of Euclid's *Elements* into language largely ideographic, using for the purpose about forty new symbols.¹ Some of his readers complained of the excessive brevity and compactness of the exposition, but Oughtred never relented. He found in John Wallis an enthusiastic disciple. At the time of Wallis, representatives of the two schools of mathematical exposition came into open conflict. In treating the "Conic Sections"² no one before Wallis had employed such an amount of symbolism. The philosopher Thomas Hobbes protests emphatically: "And for . . . your Conic Sections, it is so covered over with the scab of symbols, that I had not the patience to examine whether it be well or ill demonstrated."³ Again Hobbes says: "Symbols are poor unhand-some, though necessary scaffolds of demonstration";⁴ he explains further: "Symbols, though they shorten the writing, yet they do not make the reader understand it sooner than if it were written in words. For the conception of the lines and figures . . . must proceed from words either spoken or thought upon. So that there is a double labour of the mind, one to reduce your symbols to words, which are also symbols, another to attend to the ideas which they signify. Besides, if you but consider how none of the ancients ever used any of them in their published demonstrations of geometry, nor in their books of arithmetic . . . you will not, I think, for the future be so much in love with them. . . ."⁵ Whether there is really a double translation, such as Hobbes claims, and also a double labor of interpretation, is a matter to be determined by experience.

386. Meanwhile the *Algebra* of Rahn appeared in 1659 in Zurich and was translated by Brancker into English and published with additions by John Pell, at London, in 1668. The work contained some new symbols and also Pell's division of the page into three columns. He marked the successive steps in the solution so that all steps in the process are made evident through the aid of symbols, hardly a word

¹ Printed in Oughtred's *Clavis mathematicae* (3d ed., 1648, and in the editions of 1652, 1667, 1693). See our §§ 183, 184, 185.

⁴ *Ibid.*, p. 248.

⁵ *Ibid.*, p. 329.

of verbal explanation being necessary. In Switzerland the three-column arrangement of the page did not receive enthusiastic reception. In Great Britain it was adopted in a few texts: John Ward's *Young Mathematician's Guide*, parts of John Wallis' *Treatise of Algebra*, and John Kirkby's *Arithmetical Institutions*. But this almost complete repression of verbal explanation did not become widely and permanently popular. In the great mathematical works of the seventeenth century—the *Géométrie* of Descartes; the writings of Pascal, Fermat, Leibniz; the *Principia* of Sir Isaac Newton—symbolism was used in moderation. The struggles in elementary geometry were more intense. The notations of Oughtred also met with a most friendly reception from Isaac Barrow, the great teacher of Sir Isaac Newton, who followed Oughtred even more closely than did Wallis. In 1655, Barrow brought out an edition of Euclid in Latin and in 1660 an English edition. He had in mind two main objects: first, to reduce the whole of the *Elements* into a portable volume and, second, to gratify those readers who prefer "symbolical" to "verbal reasoning." During the next half-century Barrow's texts were tried out. In 1713, John Keill of Oxford edited the *Elements* of Euclid, in the Preface of which he criticized Barrow, saying: "Barrow's Demonstrations are so very short, and are involved in so many notes and symbols, that they are rendered obscure and difficult to one not versed in Geometry. There, many propositions, which appear conspicuous in reading Euclid himself, are made knotty, and scarcely intelligible to learners, by his Algebraical way of demonstration. . . . The *Elements* of all Sciences ought to be handled after the most simple Method, and not to be involved in Symbols, Notes, or obscure Principles, taken elsewhere." Keill abstains altogether from the use of symbols. His exposition is quite rhetorical.

William Whiston, who was Newton's successor in the Lucasian professorship at Cambridge, brought out a school *Euclid*, an edition of Tacquet's *Euclid* which contains only a limited amount of symbolism. A more liberal amount of sign language is found in the geometry of William Emerson.

Robert Simson's edition of Euclid appeared in 1756. It was a carefully edited book and attained a wide reputation. Ambitious to present Euclid unmodified, he was careful to avoid all mathematical signs. The sight of this book would have delighted Hobbes. No scab of symbols here!

That a reaction to Simson's *Euclid* would follow was easy to see. In 1795 John Playfair, of Edinburgh, brought out a school edition

of Euclid which contains a limited number of symbols. It passed through many editions in Great Britain and America. D. Cresswell, of Cambridge, England, expressed himself as follows: "In the demonstrations of the propositions recourse has been made to symbols. But these symbols are merely the representatives of certain words and phrases, which may be substituted for them at pleasure, so as to render the language employed strictly conformable to that of ancient Geometry. The consequent diminution of the bulk of the whole book is the least advantage which results from this use of symbols. For the demonstrations themselves are sooner read and more easily comprehended by means of these useful abbreviations; which will, in a short time, become familiar to the reader, if he is not beforehand perfectly well acquainted with them."¹ About the same time, Wright² made free use of symbols and declared: "Those who object to the introduction of Symbols in Geometry are requested to inspect Barrow's *Euclid*, Emerson's *Geometry*, etc., where they will discover many more than are here made use of." "The difficulty," says Babbage,³ "which many students experience in understanding the propositions relating to ratios as delivered in the fifth book of Euclid, arises entirely from this cause [tedious description] and the facility of comprehending their algebraic demonstrations forms a striking contrast with the prolixity of the geometrical proofs."

In 1831 R. Blakelock, of Cambridge, edited Simson's text in the symbolical form. Oliver Byrne's *Euclid* in symbols and colored diagrams was not taken seriously, but was regarded a curiosity.⁴ The Senate House examinations discouraged the use of symbols. Later De Morgan wrote: "Those who introduce algebraical symbols into elementary geometry, destroy the peculiar character of the latter to

¹ *A Supplement to the Elements of Euclid*, Second Edition . . . by D. Cresswell, formerly Fellow of Trinity College (Cambridge, 1825), Preface. Cresswell uses algebraic symbols and pictographs.

³ Charles Babbage, "On the Influence of Signs in Mathematical Reasoning," *Transactions Cambridge Philos. Society*, Vol. II (1827), p. 330.

⁴ Oliver Byrne, *The Elements of Euclid in which coloured diagrams and symbols are used* (London, 1847). J. Tropfke, *op. cit.*, Vol. IV (1923), p. 29, refers to a German edition of Euclid by Heinrich Hoffmann, *Teutscher Euclides* (Jena, 1653), as using color. The device of using color in geometry goes back to Heron (*Opera*, Vol. IV [ed. J. L. Heiberg; Leipzig, 1912], p. 20) who says: "And as a surface one can imagine every shadow and every color, for which reason the Pythagoreans called surfaces 'colors.'" Martianus Capella (*De nuptiis* [ed. Kopp, 1836], No. 708) speaks of surfaces as being "ut est color in corpore."

every student who has any mechanical associations connected with those symbols; that is, to every student who has previously used them in ordinary algebra. Geometrical reasons, and arithmetical processes have each its own office; to mix the two in elementary instruction, is injurious to the proper acquisition of both."¹

The same idea is embodied in Todhunter's edition of Euclid which does not contain even a plus or minus sign, nor a symbolism for proportion.

The viewpoint of the opposition is expressed by a writer in the *London Quarterly Journal* of 1864: "The amount of relief which has been obtained by the simple expedient of applying to the elements of geometry algebraic notation can be told only by those who remember to have painfully pored over the old editions of Simson's *Euclid*. The practical effect of this is to make a complicated train of reasoning once intelligible to the eye, though the mind could not take it without effort."

English geometries of the latter part of the nineteenth century and of the present time contain a moderate amount of symbolism. The extremes as represented by Oughtred and Barrow, on the one hand, and by Robert Simson, on the other, are avoided. Thus conflict in England lasting two hundred and fifty years has ended as a draw. It is a stupendous object-lesson to mathematicians on mathematical symbolism. It is the victory of the golden mean.

387. The movements on the Continent were along the same line but were less spectacular than in England. In France, about a century after Hérigone, Clairaut² used in his geometry no algebraic signs and no pictographs. Bézout³ and Legendre⁴ employed only a moderate amount of algebraic signs. In Germany, Karsten⁵ and Segner⁶ made only moderate use of symbols in geometry, but Reyher⁷ and Lorenz

used extensive notations; Lorenz brought out a very compact edition of all books of Euclid's *Elements*.

Our data for the eighteenth and nineteenth centuries have been drawn mainly from the field of elementary mathematics. A glance at the higher mathematics indicates that the great mathematicians of the eighteenth century, Euler, Lagrange, Laplace, used symbolism freely, but expressed much of their reasoning in ordinary language. In the nineteenth century, one finds in the field of logic all gradations from no symbolism to nothing but symbolism. The well-known opposition of Steiner to Plücker touches the question of sign language.

The experience of the past certainly points to conservatism in the use of symbols in elementary instruction. In our second volume we indicate more fully that the same conclusion applies to higher fields. Individual workers who in elementary fields proposed to express practically everything in ideographic form have been overruled. It is a question to be settled not by any one individual, but by large groups or by representatives of large groups. The problem requires a consensus of opinion, the wisdom of many minds. That wisdom discloses itself in the history of the science. The judgment of the past calls for moderation.

The conclusion reached here may be stated in terms of two school-boy definitions for salt. One definition is, "Salt is what, if you spill a cupful into the soup, spoils the soup." The other definition is, "Salt is what spoils your soup when you don't have any in it."
